GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

For sale by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 16, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.

Maruzen Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

Handwritten text in the left margin, possibly a page number or date.

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 16, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title and Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

angstrom(s)	mOsm	milliosmolar
adrenocorticotrophic hormone	max	maximum
adenosine diphosphate	mEq	milliequivalent(s)
adenosine monophosphate	min	minute(s)
adenosine triphosphate	ml	milliliter(s)
approximately	μl	microliter(s)
average	mm	millimeter(s)
bacillus Calmette-Guerin	mo	month(s)
twice daily	mol wt	molecular weight
degree(s) centigrade	N	normal concentration
calorie(s)	NAD	nicotinamide adenine dinucleotide
kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
millicurie(s)	NCI	National Cancer Institute
microcurie(s)	NIH	National Institutes of Health
centimeter(s)	PAS	periodic acid-Schiff
central nervous system	po	orally
counts per minute	ppb	parts per billion
deoxyribonucleic acid	ppm	parts per million
median effective dose	qid	four times daily
ethylenediamine tetraacetic acid	qod	every other day
gram(s)	QO ₂	oxygen quotient
kilogram(s)	R	roentgen
milligram(s)	RBC	red blood cells (erythrocytes)
microgram(s)	RNA	ribonucleic acid
hemoglobin	rpm	revolutions per minute
hour(s)	sc	subcutaneous
intra-arterial	sec	second(s)
intra-dermal	SGOT	serum glutamic-oxaloacetic transaminase
Immunoglobulin A	SGPT	serum glutamic-pyruvic transaminase
Immunoglobulin B	soln	solution
Immunoglobulin G	TCD	tissue culture dose
Immunoglobulin M	TCD ₅₀	median tissue culture dose
increased life span	tid	three times daily
intramuscular	UV	ultraviolet
intraperitoneal	WBC	white blood cells (leukocytes)
International Unit(s)	wk	week(s)
intravenous	wt	weight
Michaelis constant	X	times
lethal dose	yr	year(s)
median lethal dose		
molar		
micromolar		

Handwritten text in the left margin, possibly a page number or reference.

REVIEW

6001 **Report of the Conference on Modification of Mutagenic and Carcinogenic Activity, Williamsburg, Virginia, October 24-26, 1977.** (Eng) De Serres, J. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC). *Mutat Res* 54(2): 197-202; 1978.

Discussion of the results of a joint US/Japanese conference discuss factors that can modify the mutagenic and/or carcinogenic activity of environmental chemicals indicated that these factors are wide-ranging and that they include genes, enzymes, disease, several compounds, metal ions, sex hormones, and vegetable extracts. (no refs.)

6002 **Occupational Carcinogens and Their Interaction with Other Aetiological Factors.** (Eng) Wainhouse, J. A. (Regional Cancer Registry, Queen Elizabeth Medical Centre, Birmingham, England). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer (New York, NY): Vol. 2(Part 1), 2404 pp.; 1601-1608; 1978.

Studies of occupational carcinogenesis must consider, in addition to duration of exposure to the carcinogen, individual factors (age, sex, ethnic origin, personal hygiene, smoking, alcohol intake, and dietary habits), and environmental factors (pollutants in the atmosphere, water or food), climatic and geographic factors, and the urban/rural subdivision. These studies are reviewed that correlate malignancies with various working situations. A study of bladder cancer incidence in the dyestuffs industry showed that the age at onset is related to the age of first exposure. A study of lung cancer in asbestos workers indicates a synergistic effect between asbestos and cigarette smoking. It is also possible for a single substance to act as a multiple carcinogen, as evidenced by a study relating scrotal epithelioma to industrial mineral oil exposure, which also induced primary carcinomas of the testis, skin and stomach. (8 refs.)

6003 **Current Views on the Mechanisms of Chemical Carcinogenesis.** (Rus) Pliss, G. B. (N. N. Petrov Ecological Res. Inst., USSR Ministry Health, Leningrad, USSR). *Vopr Onkol* 24(9): 95-107; 1978.

Current concepts on the mechanism of chemical carcinogenesis are reviewed. In the first step of chemical carcinogenesis, the carcinogen is circulated in the body and metabolized. Metabolic activation to an ultimate carcinogen is a characteristic of practically all chemical carcinogens. Enzymes are involved in the metabolism of most carcinogens. In the second step of carcinogenesis, the ultimate carcinogen is bound to the biological substrate (nucleic acids, especially DNA) of the target cells, thereby causing cell damage. Under the effect of carcinogens, the enzyme spectrum often becomes similar to the embryonal enzyme spectrum. The contact of a cell with a carcinogen usually does not lead to immediate formation of a cancer cell, but rather to the appearance of a population of precancer cells whose malignant transformation requires further exposure to carcinogenic or cocarcinogenic factors. (92 refs.)

78-6004 **Chemical Carcinogens: How Dangerous Are Low Doses?** (Eng) Maugh, T. H. (No affiliation given). *Science* 202(4363): 37-41; 1978.

The controversy over the effects of low carcinogen doses on subsequent tumor initiation is reviewed. One view is that the dose-response curve is a straight line; that is, that a tumor can be induced at any dosage. Restated, this is the "one-hit" hypothesis: cancer is a replicable change in cellular genetics resulting from the interaction of one carcinogen molecule with a critical receptor in one cell. The opposing view is that there is a threshold, or no-effect, dose of carcinogen below which tumor initiation occurs only at a chance rate. This view is the one presently held legislatively. The "one-hit" hypothesis is supported by data on radiation-induced cancer, which follows a linear dose-response to an incidence of 0.1%. A review of 151 chemicals studied at several doses in animals showed that none were consistent with a threshold model. Proponents of the threshold hypothesis state that humans are surrounded by carcinogens, and the fact that everyone does not develop cancer indicates there must be protective mechanisms. In fact, compounds such as glutathione and vitamins A and E are able to detoxify small amounts of carcinogens in the body, as long as these systems are not overwhelmed. The body itself needs small amounts of carcinogens, such as heavy metal ions or estrogens, for proper functioning. It is generally accepted that the latent period increases as the dose is reduced. Threshold hypothesis supporters claim that at small doses, the latent period may be longer than the life of the organism. Preliminary results of a large study (the megamouse study) on the effects of low doses of carcinogen indicate that more than one mechanism of carcinogenesis may be operating. (no refs.)

- 78-6005 The Salmonella/Microsome Test for Detection of Carcinogens as Mutagens.** (Eng) Ames, B. N. (Dept. Biochemistry, Univ. California at Berkeley, Berkeley, CA, 94720); McCann, J. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 2013-2017; 1978.

Advantages of the *Salmonella typhimurium*/microsome test for detecting chemical carcinogens as mutagens are reviewed. Several improvements have made the bacteria orders of magnitude more sensitive than a simple system that just detects reversion of any mutation back to wild-type or a simple forward-mutation system. It is highly probable that chemicals found to be mutagenic in this test will turn out to be carcinogens. (19 refs.)

- 78-6006 Philadelphia Scientist Suggests an Alternate Way to Detect Nitrosamines.** (Eng) Carson, H. C. (No affiliation given). *Household & Personal Products Industry* 15(10): 59-61; 1978.

Differential pulse polarography is proposed as a suitable additional means of detecting nitrosamines and nitrite ion. (3 refs.)

- 78-6007 Practical and Administrative Aspects of the Use of Carcinogenicity Screening Tests (Letter to Editor).** (Dan) Knudsen, I. (Inst. Toxicology, State Food Res. Inst., Denmark). *Ugeskr Laeger* 140(41): 2515-2517; 1978.

The reliability of short-term in vitro carcinogenicity screening tests of chemical substances is reduced by false-positive and false-negative findings. Substances suspect in the in vitro tests cannot be justifiably banned. (15 refs.)

- 78-6008 Relationship Between Mutagenesis and Carcinogenesis.** (Eng) Trosko, J. E. (Dept. Human Development, Coll. Human Medicine, Michigan State Univ., East Lansing, MI); Chang, C. C. *Photochem Photobiol* 28(2): 157-168; 1978.

Genetic influences on the regulation of cell proliferation are discussed, and an integrative theory of carcinogenesis is offered to reconcile the mutation vs epigenetic theories of carcinogenesis, the two-stage theory of carcinogenesis, and Comings' general theory of carcinogenesis. Carcinogenic initiation seems to be the result of the induction of DNA damage, its subsequent error-prone repair and/or replication, and muta-

tion fixation. Carcinogenic promotion appears to involve depression of previously mutated but repressed genes. Therefore, a few neoplasms could arise from a mutagenic event alone if the mutated gene is in the derepressed state at a time of mutation fixation. Many tumors would arise only after there had been a mutagenic event that is followed by an epigenetic alteration of these mutated genes (2-stage theory). Some tumors can arise simply by the abnormal derepression of genes in tissues at a particular developmental stage that prevents the normal regulation of genes that influence cell division. (102 refs.)

- 78-6009 Volatile Carcinogens: Occurrence, Formation, and Analysis.** (Eng) Hoffmann, D. (Natl. Cancer Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Schmeltz, I.; Hecht, S. S.; Brunemann, K. D.; Wynder, E. L. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1943-1949; 1978.

Carcinogenicity data (humans and animals); levels in occupational environments, polluted air, and cigarette smoke; analytical methods for several volatile chemical carcinogens including vinyl chloride, chlorinated hydrocarbons, bis(chloromethyl)ether, N-nitrosamines, and hydrazines, are reviewed. (33 refs.)

- 78-6010 Analytical Methods for Polynuclear Aromatic Hydrocarbons.** (Eng) Schmeltz, I. (Natl. Cancer Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); Brunemann, K. D.; Hoffmann, D. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1973-1992; 1978.

Techniques for analyzing polynuclear aromatic hydrocarbons in tobacco smoke, air, and soil are reviewed, and the methods include various chromatographic and spectroscopic procedures, gas chromatography/mass spectrometry, and isotopic dilution. Detection data are tabulated, and some biological data are also presented. (68 refs.)

- 78-6011 Carcinogenicity Testing of Chemicals with Particular Reference to Organochlorine Pesticides.** (Eng) Reuber, M. D. (NCI Frederick Cancer Res. Center

Frederick, MD, 21501). *Sci Total Environ* 10(2): 105-115; 1978.

The testing of chemicals, particularly organochlorine pesticides, for carcinogenicity is reviewed. Classification of hepatic lesions in mice and rats, diagnostic criteria for malignant hepatic tumors in these animals, toxicity vs carcinogenicity, comparison of carcinomas and cirrhosis of the liver in animals and humans, and the significance of laboratory findings to human health are covered. (66 refs.)

8-6012 **Scared of Cancer? Don't Blame Modern Agriculture.** (Eng) Grierson, W. (Univ. Florida, Agricultural Res. and Education Center, Lake Alfred, FL). *J Farm Chemicals* 141(9): 69-76; 1978.

Whatever the causes of cancer, they long antecede the use of modern agricultural chemicals or food additives. This statement is supported by the facts that all forms of cancer except lung cancer are static or declining in the US, life expectancy has increased over the past 50 yr, there is no documented case of anyone in the US ever having been made sick by a pesticide residue legally used, and there is evidence that DDT is an anticarcinogen. (39 refs.)

8-6013 **Induced Plasma Cell Neoplasms.** (Pol) Salwa, J. (Zaklad Immunologii Nowotworow, Instytut Immunologii i Terapii Doswiadczalnej PAN, Czerna 12, 53-114 Wroclaw, Poland). *Postepy Hig Med Dosw* 31(6): 803-807; 1977.

The induction and antigenic properties of plasmacytomas are reviewed. Plasmacytomas can be induced in mice by 2,6,10,14-tetramethylpentadecane, 2,6,10,14-tetramethylhexadecane, and Abelson's virus. (51 refs.)

8-6014 **Health Problems Associated with Selected Petrochemicals: Benzene, Chlorinated Hydrocarbons, and Styrene-Butadiene Rubber.** (Eng) Lemen, R. A. (Div. Surveillance, Hazard Evaluations and Field Studies, Natl. Inst. Occupational Safety and Health, U.S. Post Office and Courthouse Building, Cincinnati, OH, 45202); Brown, P. P.; Rinsky, R. A.; Young, R. J.; Meinhardt, T. J. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1979-1891; 1978.

Hazards associated with occupational exposure to benzene, a recently recognized leukemogen; chlorinated hydrocarbons, known to be hepatotoxic and potentially carcinogenic and mutagenic to humans; and styrene-butadiene rubber, which has been connected with an increase in lymphatic and hematopoietic cancer, are reviewed. (66 refs.)

78-6015 **Structure and Carcinogenic Activity Relationships in the Benz(a)anthracene Series.** (Eng) Newman, M. S. (Chemistry Dept., Ohio State Univ., Columbus, OH). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 2093-2096; 1978.

The relationship between the structure and carcinogenicity of the 12 monomethylbenz(a)anthracenes and 9 of the possible nuclear monofluorinated-7-methylbenz(a)anthracenes is considered. It is hypothesized that two types of metabolism, a detoxification process and a carcinogenic process, are involved. Because 7-methylbenz(a)anthracene (7-MBA) is the most potent of the monomethyl derivatives, the 7-position is the spot at which detoxification is initiated. Because only 5-fluoro-7-methylbenz(a)anthracene is completely inactive, the 5-position is the spot at which the carcinogenic process is initiated. The fact that 1-, 2-, 3-, and 4-fluoro-7-methylbenz(a)anthracene are only slightly active indicates that the angular ring may also be involved in carcinogenesis. Steric effects are invoked to account for the moderate activity of 6- and 8-methylbenz(a)anthracene, for the fact that 7,12-dimethylbenz(a)anthracene is a more potent carcinogen than 7-MBA (the added methyl group at the 12-position produces strain due to overcrowding, which renders the molecule more reactive), and for the carcinogenicity of 12-methylbenz(a)anthracene, which does not contain a methyl group at the 6-, 7-, and 8-positions. The carcinogenicity of 7-MBA is caused by oxidative metabolism on the 7-methyl group, which results in the formation of an alkylating agent. The hypothesis is supported by metabolic studies using *Escherichia coli* and by carcinogenicity tests. (12 refs.)

78-6016 **Effects in Animals of Chronic Administration of Spironolactone--A Review.** (Eng) Lumb, G. (G. D. Searle & Co., 4901 Searle Pkwy., Skokie, IL, 60077); Newberne, P.; Rust, J. H.; Wagner, B. *J Environ Pathol Toxicol* 1(5): 641-660; 1978.

Studies of the effect of chronic administration of spironolactone to rats, dogs, and monkeys are reviewed. The animals were treated for up to 104 wk with daily dose levels (0-500 mg/kg) that were often higher than 100 times the recommended human dose. The pituitary, adrenals, and kidneys of

all animals showed no significant changes. Histological changes were noted in the rat liver, thyroid, and male internal genitalia. There were also alterations in monkey testes and male mammary glands. There was no evidence that spironolactone is tumorigenic or carcinogenic. (33 refs.)

- 78-6017 The Crudeness of Coal Tar.** (Eng) Rasmussen, J. E. (Dept. Dermatology, State Univ. New York at Buffalo, Children's Hosp. Buffalo, Buffalo, NY). *Prog Dermatol* 12(5): 23-29; 1978.

The toxicology of coal tars is reviewed with emphasis on their carcinogenicity. Coal tars are known to contain four types of carcinogens: complete carcinogens, organ-specific carcinogens, tumor-promoting agents and cocarcinogens, and lymphoma-inducing naphthylenes. Industrial exposure to coal tar has been associated with an increased incidence of cutaneous malignancies, primarily on the sun-exposed areas of the skin but also on the scrotum. Larger studies are needed, however, to determine the risk factor for both external and internal cancers following coal tar exposure. (69 refs.)

- 78-6018 Health Effects of Petroleum Extender Oils.** (Eng) Low, H. (Shell Oil Co., One Shell Plaza, Houston, TX, 77001). *J Elastomers Plast* 10(3): 229-240; 1978.

Experimental and epidemiological studies of the health effects of extender oils, high-boiling (315-538 C) fractions of petroleum that have been put through several refining steps, are reviewed. The skin and the pulmonary system are most likely to be exposed to these oils. Both skin painting and inhalation studies with various animal species have confirmed their carcinogenic potential. Epidemiological studies of workers exposed to oil, oil vapor, and oil mists in various occupational settings (ie, oil refineries and printing and metal working industries) have given ambiguous results. The health effects of exposure range from no apparent effect to excessive mortality. Significantly elevated mortality from cancer of the buccal cavity and pharynx was observed in one study of newspaper pressmen in the early and middle working years (20-54 yr old). Commercial pressmen showed little excess mortality from cancer of the buccal cavity, but they had a significant excess of cancer of the pancreas between ages 20 and 54 and rectal cancer after age 65. However, in another study involving 460 pressmen and 700 controls, no statistically significant increase in mortality rates was found. In a study of refinery workers, mortality from digestive cancer and all malignant neoplasms was higher in men with the lowest estimated exposure to atmospheric hydrocarbons, but respiratory cancer increased with increased exposure. (26 refs.)

- 78-6019 Lung Cancer, Smoking, and Atmospheric Pollution.** (Eng) Hansford-Miller, F. (No affiliation given). *Clean Air* 8(30): 27-31; 1978.

The premise is put forth that the increase in lung cancer during the last hundred years is not due primarily to cigarette smoking but rather to the increase in CO₂ in the atmosphere as a result of the industrial revolution and other associated factors related to the earth's atmosphere. Combustion of fossil fuels increases the amount of CO₂ discharged into the atmosphere by 2 x 10⁹ tons/yr. Up to half the amount of carbon trapped in virgin grassland is lost upon cultivation. The burning of lime in cement production is another major contributor of atmospheric CO₂. The current CO₂ level of 330 ppm in the atmosphere is estimated to be increasing at a rate of 1 ppm/yr. Human lungs evolved at a constant CO₂ level, since 1850 this level has changed radically, as have the ratios of CO₂/O₂ and 14C/12C. The latter is due to the fact that fossil fuels are essentially devoid of C14. Graphs showing there is a very strong correlation between the incidence of lung cancer mortality and the combustion of fossil fuels is suggested that the inability of humans to adapt to the rapid changing atmospheric levels has resulted in current lung cancer increases. (27 refs.)

- 78-6020 The Role of Cytochrome P-450 in the Toxicity of Xenobiotics.** (Eng) Lampe, J. (Central Institute of Molecular Biology, Dept. Biocatalysis, Acad. Sciences GDR, Lindenberger Weg 70, DDR-115 Berlin, E. Germany); Kerschak, G. *Pharmazie* 33(7): 407-411; 1978.

Initiation of the formation of active metabolites from halogenated aliphatic and aromatic hydrocarbons, polycyclic aromatic hydrocarbons, aflatoxins, nitrosamines, and aromatic amines by the cytochrome P-450-dependent enzyme system is reviewed. (101 refs.)

- 78-6021 Chapter XVII--Occupational Safety and Health Administration, Department of Labor. Part 1910 - Occupational Safety and Health Standards: Occupational Exposure to Acrylonitrile (Vinyl Cyanide).** (Eng) Brinkerhoff, G. (Office Compliance Programs, Rm. N-3112, Occupational Safety and Health Admin., Third St. and Constitution Ave., NW, Washington, DC, 20210). *Federal Register* 43(192): 45762-45819; 1978.

The final standard established by the Occupational Safety and Health Administration (OSHA) for exposure to acrylonitrile (AN; vinyl cyanide), which becomes effective November 2, 1978, is delineated in detail. Based on the results of experimental studies that have shown excess tumor incidences in AN-exposed animals and on indications of a cancer excess

Among workers exposed to AN, OSHA concluded that the compound poses a carcinogenic risk to workers. In addition, AN is mutagenic, an effect observed for other carcinogenic chemicals. The permissible limit of occupational exposure to AN was set at 2 ppm, as an 8-hr time-weighted av concentration with a ceiling level of 10 ppm for any 15-min period during an 8-hr day. In addition, an action level of 1 ppm was established as an 8-hr time-weighted av. Provision is made for specific exemptions from the standard for the processing, handling, and use of acrylic and modacrylic fibers, N-butadiene-styrene/styrene-AN resins, nitrile barrier resins, and nitrile rubbers when these materials are in the form of finished polymers. The standard requires that employee exposures be controlled by engineering and work practices, supplemented by respiratory and other protective equipment in limited situations. It also requires the measurement of employee exposure, employee training, medical surveillance, and recordkeeping. (no refs.)

78-6022 The Health of Women in the Pharmaceutical and Chemical Industries. (Eng) Cuthbert, J. W. May & Baker, Ltd., Dagenham Essex RM10 7XS, England). *Occup Med* 20(9): 601-604; 1978.

Changes in the pattern of women's employment, expansion of the chemical industry, and changes in legislation have increased the exposure of women to potential chemical mutagens, teratogens, and carcinogens, and advanced knowledge in medicine and toxicology has heightened the awareness of this exposure. (19 refs.)

78-6023 Pleural Reactions to Environmental Agents. (Eng) Anderson, H. A. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY, 10029); Selikoff, J. *Fed Proc* 37(11): 2496-2500; 1978.

Radiographically evident pleural reactions to asbestos are described. Both pleural calcification (PC) and pleural thickening (PT) are seen in chest x-rays of asbestosis patients. Several studies have indicated that there is a long latent period before the appearance of pleural changes following occupational exposure to asbestos. Both PC and PT are uncommon with < 10 yr of exposure. PT and parenchymal fibrosis begin to be seen after 10-11 yr, and PC becomes common after 30 yr. In a study of 626 household contacts of workers employed in an asbestos factory, PT was the most prevalent radiographic abnormality (19%). PC was present in 8%, minimal parenchymal changes in 16%. These changes were significantly more prevalent among the household contacts than among an age- and sex-matched control group from the same area without known asbestos exposure. The prevalence of abnormalities among household contacts increased with duration of the workers' employment. It should become evident in the next 10 yr whether the levels of asbestos exposure in people living in the vicinity of asbestos plants and in household con-

tacts of workers were sufficient to cause serious disease. (30 refs.)

78-6024 Role of Pineal Gland in Etiology and Treatment of Breast Cancer. (Eng) Cohen, M. (Clinical Pharmacology Branch, NCI, NIH, Bethesda, MD, 20014); Lippman, M.; Chabner, B. *Lancet* 2(8094): 814-816; 1978.

The hypothesis is put forth that diminished pineal gland function and the subsequent inhibited secretion of melatonin may promote the development of human breast cancer (BC). BC has a known relationship with increased levels of secreted estrogen: 65% of BC cases have estrogen and progesterone receptors, and a relationship has been shown between BC and factors indicating a long exposure to estrogens, such as early menarche, late menopause, and few pregnancies. The pineal gland regulates gonadal function by the feedback inhibitory effect of melatonin on gonadal development and maturation; in fact, a specific melatonin receptor in peripheral gonadal tissue has recently been demonstrated. Therefore, it can be assumed that altered pineal function would release estrogen from the suppressive action of melatonin, and this excess estrogen could induce BC. Several lines of evidence have been developed to support this hypothesis. The rate of pineal calcification in populations and the incidence of BC are strongly correlated. Precocious sexual maturation is seen in children with pineal tumors. Female psychiatric populations, treated with serum-melatonin-raising phenothiazines, have a lower incidence of breast cancer. Finally, studies show that melatonin may influence the development of tumors in animals. If melatonin levels are found to be related to BC, this relationship would be of great value in screening for individuals at high risk. (35 refs.)

78-6025 Radiation Leukemia in Humans. (Fre) Tubiana, M. (Institut Gustave-Roussy, F-94800 Villejuif, France). *Schweiz Med Wochenschr* 108(41): 1563-1568; 1978.

The occurrence of leukemia in humans exposed to various doses and types of radiation is reviewed. The risk of leukemia from low doses of radiation such as those used in radiodiagnosis and from total body irradiation with doses exceeding 100 rads of x-rays or lower doses of neutrons was compared. Quantitative data on the incidence of leukemia in survivors of the atomic bomb explosions in Japan, in patients irradiated for ankylosing spondylitis or gynecological pathology, or in radiologists are reviewed. The dose-effect relationship between radiation and leukemia development appears to be curvilinear for large doses. The frequency of leukemia in subjects exposed to low doses of radiation, such as persons exposed occupationally or those living in the vicinity of a nuclear power station, is tabulated from literature studies. Linear extrapolation should not be used to evaluate the risk of small doses of radiation (doses in the range of a millirad). Studies of the effect of radiation in utero give conflicting results, although it appears that the small doses used for radiodiagnosis

do not present a risk. Literature reports on the increased rate of leukemia among patients treated with combination radiation and chemotherapy are reviewed. (17 refs.)

- 78-6026 Hormonal Steroid Contraceptives: A Further Review of Adverse Reactions.** (Eng) McQueen, E. G. (Dept. Pharmacology, Univ. Otago Medical Sch., P.O. Box 913, Dunedin, New Zealand). *Drugs* 16(4): 322-357; 1978.

The adverse effects of oral contraceptives (OC) are reviewed extensively. Reports of benign hepatomas in women taking these drugs are numerous. A small number of these tumors have shown malignant change. A possible etiological association with steroid-induced hyperplasia of intracellular organelles is suggested. A positive association of sequential OC and endometrial adenocarcinoma and a negative association of OC and breast cancer are also suggested. (144 refs.)

- 78-6027 Role of Exogenous Female Hormones in Altering the Risk of Benign and Malignant Neoplasms in Humans.** (Eng) Thomas, D. B. (Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104). *Cancer Res* 38(11, part 2): 3991-4000; 1978.

Clinical and epidemiological evidence for the association of exogenous estrogens and the development of neoplasms of the breast, female genital system, or liver is reviewed. In utero exposure to diethylstilbestrol can cause clear cell adenomas of the vagina and cervix. Oral contraceptives very probably cause hepatic cell adenomas but reduce the risk of cystic disease and fibroadenomas of the breast. There is also strong evidence that various forms of estrogens given around the time of menopause increase the risk of endometrial carcinoma and that sequential oral contraceptives may also be a cause of this neoplasm. There is no consistent or conclusive evidence that any form of exogenous estrogens alters the risk of neoplasms of the breast or ovary or that oral contraceptives cause focal nodular hyperplasia of the liver or cervical neoplasia. However, recent studies suggest that the risk of these neoplasms may be increased, at least in some subgroups, by exposure to one or more forms of exogenous estrogens. (98 refs.)

- 78-6028 Steroid Hormones and Endometrial Cancer.** (Eng) Siiteri, P. K. (Dept. Obstetrics, Gynecology and Reproductive Sciences, Univ. California at San Francisco Sch. Medicine, San Francisco, CA, 94143). *Cancer Res* 38(11, part 2): 4360-4366; 1978.

Factors that increase the risk of endometrial cancer, including obesity, nulliparity, late menopause, diabetes mellitus, hypertension, polycystic ovarian disease, hepatic disease, and ovarian tumors, are reviewed. Exogenous estrogens may play a causal role in the development of endometrial carcinoma

in some individuals. The increased risk among estrogen users ranges from 3 to 8 and appears to be dose- and duration-dependent. Estrogen users who develop cancer do not exhibit any of the increased risk factors. Many of the conditions that place women at increased risk of endometrial cancer (eg, obesity, hepatic disease) are associated with an elevated production of estrone in peripheral (nonendocrine) tissues from circulating androstenedione. Neither the exact tissue site nor mechanism of conversion has been established. The fact that the constitutional features that have long been associated with an increased risk of endometrial cancer are also associated with increased peripheral estrogen production is a strong argument for the participation of endogenous estrogens in the development of endometrial cancer. (74 refs.)

- 78-6029 Cervical Cancer and Its Prophylaxis (Letter to the Editor).** (Dan) Clemmesen, J. (Cancerregisteret, Copenhagen). *Ugeskr Laeg* 140(38): 2341-2343; 1978.

Epidemiological data on cervical cancer morbidity are reviewed, and the etiology of this cancer is discussed. The morbidity rates per 100,000 persons, found in the 1950's, were 38.3 in Copenhagen, 17.2 in rural areas of Denmark, 4.4 among Jewish women in New York, 17.1 among other whites in New York, and 32.8 among whites and 70.4 among blacks in other parts of the US. The low incidence of cervical cancer among Jewish women cannot be explained by circumcision. Epidemiological studies and various observations clearly show that early sexual activity and promiscuity are predisposing factors for cervical cancer. (15 refs.)

- 78-6030 Identification of Tumor Susceptibility of Individuals at High Risk for the Development of Cancer.** (Eng) Rawson, R. W. (Univ. Texas System Cancer Center, Houston, TX). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer, New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1493-1512; 1978.

Factors that can identify high-cancer-risk individuals and/or populations are reviewed, and they include host or intrinsic factors (genetic, congenital, and immune deficiency disorders), acquired nonneoplastic diseases, previous cancers), environmental factors (demographic, geographic, occupational, radiation, air pollution, viruses), and individual living patterns (tobacco, alcohol, diet, drugs, sexual practices). (7 refs.)

- 78-6031 An Epidemiological Perspective of the Biology of Cancer.** (Eng) Doll, R. (Univ. Oxford, Oxford, England). *Cancer Res* 38(11, part 1): 3573-3583; 1978.

cancer epidemiology data are reviewed to determine if they contribute to defining a mechanism of carcinogenesis. There is no evidence for genetic susceptibility to cancer as a whole, but there are differences in susceptibility to individual types of cancer. Epidemiological evidence suggests a possible role for an infectious viral agent in African Burkitt's lymphoma, Hodgkin's disease, cervical cancer, and chondrosarcomas. The incidence of several types of cancer increases after 2 yr of treatment with immunosuppressive drugs. The incidence of leukemia and lymphoreticular tumors is much greater in patients with certain immunodeficiency syndromes than in normal persons, but it is not clear whether the cancers are caused by the immunodeficiency or associated with it because of a common cause. Susceptibility to radiation-induced cancer increases with age, perhaps as a result of a progressive breakdown in the efficiency of immunosurveillance with age. Studies on tobacco smoking and lung cancer incidence indicate that the incidence increases with duration of exposure and dose, independently of age. The trend in smokers who stop smoking shows an initial fall in incidence followed by an increase, which keeps the rate ahead of that in lifelong nonsmokers. The simplest explanation for these data is that cancer production is a multistage process and that the various stages represent a series of discrete cellular changes that cumulatively result in the production of a malignant clone. (45 refs.)

6032 **Cancer and the Environment.** (Eng) Thomas, H. F. (MRC Epidemiology Unit, Cardiff, Wales). *Environ Health* 86(10): 232-233; 1978.

The relationships between the environment and human cancers, 75% to 90% of which are estimated to be environmentally caused, are considered. The cultural environment is the most important factor in cancer etiology, and it comprises smoking, drinking, and eating habits. Agents in the general and occupational environments do not appear to be important causes of cancer. In one report, it is argued that many of the most potent carcinogens have not been in use for the probable latent interval (25-30 yr) before chemical cancers become apparent. Likewise, cancers due to congenital, hereditary, iatrogenic, or viral causes appear to account for a very small proportion of the overall cancer incidence. The interaction of different agents, eg, asbestos and cigarettes, may increase the risk synergistically. (14 refs.)

6033 **Some Current Concepts in Intestinal Bacteriology.** (Eng) Moore, W. E. (Anaerobe Lab., Virginia Polytechnic Inst. and State Univ., Blacksburg, VA, 24061); Cato, E. P.; Holdeman, L. V. *Am J Clin Nutr* 31(10): 833-842; 1978.

Intestinal bacteriology and its possible relevance to colon cancer etiology are discussed. Recent studies indicate the presence in all human populations of intestinal bacteria that are

capable of metabolizing sterols to carcinogens. However, comparisons of fecal flora in high- and low-colon cancer risk populations suggest that the relative proportions of certain bacterial species within a genera may be correlated with colon cancer incidence. In low-risk African and Japanese populations and high-risk North Americans, a positive correlation was noted between colon cancer and *Bacteroides vulgatus*, *Bacteroides distasonis*, and *Peptostreptococcus productus*. There was an inverse relationship between colon cancer and *Eubacterium aerofaciens* II, *Bacteriodes fragilis*, and *Escherichia coli*. Because flora of the transverse and descending colon and rectum are in the stationary growth phase, fecal bacteria adequately represent colonic flora. Bacterial response can be affected by epinephrine release during fear or anger reactions. Diet manipulation does not appreciably change intestinal flora, but high-fat diets may be involved in colon carcinogenesis by providing different substrates for bacterial action. Although technical problems make this type of study extremely difficult, future work must concern itself with the identification of carcinogens in the intestine, the bacteria responsible for their presence, and the factors that control their production. (59 refs.)

78-6034 **Common Intestinal Bacteria in Etiology of Colon Cancer (Meeting Abstract).** (Eng) Storstebecker, T. P. (Akerbyvagen 282, Taby, Stockholm, Sweden). *Acta Med Scand Suppl* (621): 46; 1978. (2 refs.)

78-6035 **Fecal Flora in Different Populations, with Special Reference to Diet.** (Eng) Finegold, S. M. (Infectious Disease Section, Wadsworth Veterans Admin. Hosp., Los Angeles, CA, 90073); Sutter, V. L. *Am J Clin Nutr* 31(10): S116-S122; 1978.

Studies of the fecal microbial flora of different populations are summarized. Two groups of Japanese-Americans, one on a Japanese diet and the other a western diet, exhibited significant differences in the occurrence of seven intestinal species or genera. Similarly, patients with multiple adenomatous polyposis differed significantly from controls in nine types of organisms. In both studies, however, there was little overlap in the species present in high- vs low-incidence colon cancer groups, so the differences could have been the result of chance variation. In neither study was there a significant difference in presence of *Clostridium paraputrificum* organisms. In a study of Seventh-Day Adventists (SDA's), *Clostridium septicum* and *Clostridium tertium* were significantly more common in non-SDA controls than in either vegetarian or non-vegetarian SDA's. Nonvegetarian SDA's, compared with other previously studied nonvegetarian groups, showed a much higher incidence of lactobacilli and a lower incidence of *Clostridium perfringens*. These and other studies demonstrated that fecal flora are remarkably constant, with only 21 organisms or groups of organisms differing in frequency between high- and low-incidence colon cancer populations.

These organisms should be studied for their ability to produce carcinogens or cocarcinogens from substrates such as bile acids. (21 refs)

- 78-6036 Role of Diet and Nutrition in Cancer Cause, Prevention and Treatment.** (Eng) Gori, G. B. (Diet, Nutrition and Cancer Program, NCI, Building 31, Room 11A-03, Bethesda, MD, 20014). *Bull Cancer (Paris)* 65(2): 115-126; 1978.

The roles of diet and nutrition as etiologic factors in cancer incidence are reviewed. Epidemiologic evidence, including that obtained from studies of several migrant populations and ethnic groups, supports the hypothesis that different dietary constituents rather than other environmental contaminants are important in the cause of certain types of cancer. Fat consumption has been associated with some cancers, particularly bowel cancer. According to one theory, an excessive fat intake modifies the metabolism of cholesterol, bile acids, and neutral steroids in the intestine, as well as the metabolism and secretion of steroid hormones in the circulation. Bile acids secreted in the intestine could be degraded by intestinal bacteria to form carcinogens, or the altered metabolism of steroid hormones could impose unnatural burdens on cellular receptors of specific target tissues (uterus or breast). Animal studies strongly confirm the results of epidemiologic studies in humans. (74 refs)

- 78-6037 Diet and Breast Cancer: A Review.** (Eng) Hankin, J. H. (Sch. Public Health, Univ. Hawaii, 1960 East-West Road, Honolulu, HI, 96822); Rawlings, V. *Am J Clin Nutr* 31(11): 2005-2016; 1978.

Human breast cancer (BC) is a multifactorial disease that is probably influenced by dietary intake. Studies of geographical variations in diet have shown that North America and northern Europe are high risk areas for BC, but countries in Africa and Asia are relatively low risk areas. The association of early menarche with higher risk and early first pregnancy with lower risk suggest that tumor initiation or inhibition may be determined in adolescence. Obesity may contribute to BC by influencing hormone synthesis and metabolism. Although dietary fat has been implicated in BC, dietary proteins, cholesterol, carbohydrates, and calories may also be involved. Studies of mammary tumor development in rodents indicate that tumorigenesis is associated with polyunsaturated rather than saturated fats; however, nutritional factors, including fat type, are more likely to act as promoters rather than initiators of tumorigenesis. Endocrinologic data indicate that women with a low ratio of estradiol to estrone and estrone are at high risk for BC. In rats, a high-fat diet increased serum prolactin levels and promoted mammary tumor development by 7,12-dimethylbenz(a)anthracene, but studies of prolactin levels in BC patients have yielded inconsistent results. The

need for further research in all of these areas is emphasized. (91 refs)

- 78-6038 Workshop V--Fiber and Cancer: Summary and Recommendations.** (Eng) Burkitt, D. P. (Filiation given). *Am J Clin Nutr* 31(10): S213-S215; 1978.

Mechanisms whereby lack of fiber may promote colorectal cancer or whereby fiber may protect against this cancer are reviewed briefly. Applicable fecal parameters include neutral steroids, bile salts, and lipids; ammonia levels; pH; enzyme activities; mutagenicity/carcinogenicity; transit time; and water content; and microbial flora. (no refs)

- 78-6039 Recent Progress in Dietary Fiber (Plantix) and Human Nutrition.** (Eng) Spiller, G. A. (Syntex Res., Palo Alto, CA); Shipley, E. A.; Blake, J. A. *Crit Rev Food Sci Nutr* 10(1): 31-90; 1978.

Research performed since 1975 on the role of dietary fiber (plantix) in human nutrition is reviewed. A high low-plantix diet has been correlated with a high incidence of colorectal cancer. The significance of plantix may not be an affecter of transit time/constipation but rather as a diluent of colonic contents. However, other factors such as naturally occurring antioxidants (vitamins E and C, selenium, etc.) and vitamin A may also play a key role in the etiology of colorectal cancer. Many plantix polymers have a great capacity to interact with other dietary components. A study of 198 I colon cancer patients showed that they had a significantly lower fiber consumption. Study of the etiology of colorectal cancer in Chile, where the incidence is very low, revealed that the daily diet is a high-carbohydrate, low-protein, low-fat, one rich in plant fibers. One hypothesis advanced is that plantix-associated factors, ie, lectin, may be involved in protecting against colon cancer. Several possible mechanisms by which the body's response to undigested lectin in the colon would protect against intestinal cancer are given. Although many factors probably contribute to colon cancer, a higher intake of plantix and antioxidants may help to prevent the disease. (161 refs)

- 78-6040 Interaction of Dietary Fiber with Other Dietary Components: a Possible Factor in Certain Colorectal Cancer Etiologies.** (Eng) Spiller, G. A. (Syntex Res., 3401 View Ave., Palo Alto, CA, 94304). *Am J Clin Nutr* 31(10): S231-S232; 1978.

The concept that dietary fiber, or "plantix" (ie, all polymers of plant materials that are indigestible by human digestive enzymes) is an integral part of gastrointestinal physiology which cannot be studied purely on the basis of its presence or absence, is discussed. Plantix must be considered in the

its interaction with other nutrients, and this pattern must be precisely identified. Plantix may affect the feces by altering pH, general composition, or transit time. It may affect colonic microflora directly, serving as a nutrient for certain organisms, or it may carry other constituents to the colon that would not arrive there otherwise. It may alter pH, the elimination rate of microfloral metabolites or toxins, or dilute carcinogens. Finally, it can alter the location and absorption rate of nutrients and the reabsorption of metabolites along the intestine. All these factors suggest that a more complex means of studying plantix is necessary, one that considers the interactive facets of this dietary component. (3 refs)

78-6041 The Relationship Between Bowel Cancer and Fiber Content in the Diet. (Eng) Walker, A. R. (Human Biochemistry Res. Unit, South African Inst. Medical Res., P.O. Box 1038, Johannesburg 2000, South Africa). *Am J Clin Nutr* 31(10): S248-S251; 1978.

A review of data on colon cancer in South African blacks (SAB) indicates that the disease is very uncommon in this population. This rarity is not attributed to lack of adequate case reporting since high and/or increased incidence rates have been reported for cancers at certain other sites. There has been an increase in standard of living and urbanization of SAB; but in spite of the westernization in diet and way of life, the risk of colon cancer remains the same. Since the dietary changes which accompany urbanization (decreased crude fiber in diet, longer fecal transit time, lower frequency of defecation and less feces voided per day) have been correlated with increases in colon cancer elsewhere, intrinsic factors seem to be protecting SAB. The existence of this protective factor is suggested by the unchanged incidence of appendicitis, another disease which is usually seen to increase after urbanization affects diet. Further research is needed on bowel physiology fecal chemical composition, and enzymatic markers of intestinal microfloral activity in SAB. (19 refs)

78-6042 Diet and Cell Growth Modulation by Ammonia. (Eng) Visek, W. J. (Sch. Basic Science, Dept. Food Science, Univ. Illinois, Urbana, IL, 61801). *Am J Clin Nutr* 31(10): S216-S220; 1978.

The role of dietary fiber in the production and metabolism of ammonia by host cells, digestive enzymes, and gastrointestinal microflora is discussed. Fiber passes through the small intestine to the cecum and colon, where bacteria use it as an energy source for protein synthesis, in which the necessary nitrogen is supplied by ammonia. By facilitating the incorporation of ammonia into protein or its dilution, fiber reduces the harmful effects of ammonia on the gastrointestinal mucosa. Furthermore, fiber fermentation yields fatty acids that decrease colon pH and provide anions to trap free ammonia. Ammonia can induce cell proliferation, which enhances neoplastic transformation by increasing errors in DNA copying,

increasing code breaking actions of mutagens present in sub-threshold doses, or unmasking latent DNA changes caused by mutagens. Ammonia also alters cell life-span and metabolism, and enhances virus production. Although it does not transform cells per se, the incidence of polyps and cancers is highest in colonic areas with the highest ammonia concentrations. The role of fiber in removing free ammonia from the colon may explain the low incidence of colon cancer in populations with high-dietary fiber. (48 refs)

78-6043 Colonic-Rectal Cancer: Fiber and Other Dietary Factors. (Eng) Burkitt, D. P. (Unit Geographical Pathology, St. Thomas' Hosp., London SE1 7EH, England). *Am J Clin Nutr* 31(10): S58-S64; 1978.

The epidemiological evidence supporting the low fiber-high fat hypothesis for colon cancer etiology is comprehensively reviewed. Large bowel cancer bears a direct and constant relationship to economic development and westernization. Furthermore, within high incidence locales, there is an urban-rural correlation, with colon cancer being more prevalent in the urban areas. Chronological changes have also been documented; eg, the incidence rate in American blacks has increased significantly in the past generation. Groups that have immigrated from low to high incidence areas, notably the Japanese in Hawaii and California, show an increase in cancer incidence. Occurrence of other diseases, such as adenomatous polyps, diverticular disease, hiatus hernia and appendicitis, correlates with appearance of colon cancer, suggesting that all may result, at least to some degree, from common factors. Investigation has frequently centered on differences in fecal composition as a result of westernization and the accompanying decrease in dietary fiber and increase in fat intake. Hypotheses that have been put forth to explain how these dietary changes could result in cancer include decreased transit time, decreased dietary dilution, accumulation of toxins and carcinogens, or interactions between bacterial flora and dietary constituents. (52 refs)

78-6044 Models Relating Ultraviolet Light and Non-melanoma Skin Cancer Incidence. (Eng) Green, A. E. (ICAAS, Univ. Florida, Gainesville, FL, 32611); Hedinger, R. A. *Photochem Photobiol* 28(2): 283-291; 1978.

Various approaches used to relate UV light doses to non-melanoma skin cancer (SC) incidence are reviewed. Three spectral response functions (DNA, Coblenz-Stair erythema response, and Robertson-Berger meter response) that have been used in epidemiological UV-SC studies are illustrated. If the DNA response function is the relevant one in SC, as seems most reasonable from a biophysical viewpoint, then a true dose-response relationship could depart significantly from an apparent relationship obtained by comparing meter readings with incidence data. Based on standard statistical

or epidemiological approaches, a double power law model seems to be as good a dose-response relationship as can be determined from Third National Cancer Survey data, which span a narrow range of annual doses. Various inductive approaches to dose-response relations are also reviewed. Despite the inconsistency of epidemiological data collected in different parts of the world, the data tend to favor multiple cause or age-exposure models over reciprocity, dose potency, and separable models. Both favored models are biophysically reasonable. Thus, the notion that there is more than one cause of SC is also suggested by evidence pointing to chemical carcinogens. The idea that age specific incidence rates of SC might depend on age and exposure is compatible with modern ideas on the degradation of immunological defenses. The application of the mathematical machinery of Reliability Theory to models relating UV light and nonmelanoma SC incidence is also illustrated. (54 refs)

- 78-6045 Ultraviolet Light Mutagenesis in *Escherichia coli* (Meeting Abstract).** (Eng) Volkert, M. R. (Dept. Molecular Biology, Univ. California, Berkeley, CA, 94720). *Can J Genet Cytol* 20(3): 438; 1978. (no refs)

- 78-6046 Solar Radiation and Skin Cancer.** (Nor) Fyrand, O. (Rikshospitalet, Hudavdelingen, Norway). *Tidsskr Nor Laegeforen* 98(24): 1139-1140; 1978.

In this literature review, the relationship between exposure to UV rays, natural or artificial, and precancerous changes in the skin and skin cancer is confirmed. The effect of the exposure is cumulative. A causal relationship between exposure to light and malignant skin melanoma is probable. (13 refs)

- 78-6047 Comparison of Relative Risk from Radiation Exposure and Other Common Hazards.** (Eng) Kelsey, C. A. (Radiology Dept., Univ. New Mexico, Albuquerque, NM, 87131). *Health Phys* 35(2): 428-430; 1978.

Three comparisons are presented that have proven useful in putting effects from accidental or occupational exposure to radiation in perspective and in assisting radiation workers in evaluating the relative risks due to radiation exposure: (1) comparison of hazards from radiation exposure to hazards from various accidents in the US, (2) relative accident rates for various occupations in the US, and (3) comparison of the health hazards associated with cigarette smoking and radiation. Results are reported in terms of hazard/rem (roentgen equivalent man) exposure, assuming that there is no recovery from radiation injury and that the effect of 1 rem is the same whether delivered over periods of 1 mo, 1 yr, or 5 yr. Deaths per yr per million persons are 9 for each rem of radiation compared to 4,780 for cardiovascular disease. Among 15 oc-

cupations, radiation workers have the lowest risk of job-related accidental death (0.02 relative death rate) and miners highest (6.2). The life shortening effect of smoking one cigarette is equivalent to exposure to 2.5 mm radiation. (10 refs)

- 78-6048 A Stochastic Model of Carcinogenesis Incorporating Certain Observations from Chemical and Radiation Dose-Response Data.** (Eng) Brodsky, A. (Office of Standards Development, U.S. Nuclear Regulatory Commission, Washington, DC, 20555). *Health Phys* 35(3): 421-428; 1978.

A stochastic model of carcinogenesis that incorporates phenomena regarding the sequential interactions of carcinogens is presented. There is preliminary evidence from animal experiments that this model is consistent with observed quantitative dose-response relationships. An example is dose-response relationships for radiation carcinogenesis (tumors in mice implanted with Ru^{106} pellets or administered Ce^{144} intratracheally). The two-step sequential stochastic model may provide an alternative model to the log-normal model for interpreting a broad range of radiobiological toxicological effects. (9 refs)

- 78-6049 The Combined Effects of Ionizing Radiation and Smoking in the Development of Bronchogenic Carcinoma.** (Ger) Schuttmann, W. (Hauptabteilung Strahlenschutzmedizin, Staatlichen Amtes für Atomsicherheit Strahlenschutz der DDR, Waldowallee 117, DDR-1157 Berlin, E. Germany). *Z Erkr Atmungsorgane* 150(3): 243-247; 1978.

Evidence that smoking increases the probability of respiratory tract cancer developing in individuals previously exposed to ionizing radiation is reviewed. Uranium miners who smoked had a respiratory tract cancer rate of 17/10,000 person-yr, but nonsmoking miners had a rate of only 1.7/10,000 person-yr. Miners who smoked more than one pack of cigarettes/day had a significantly shorter average tumor-latency period than nonsmokers. This type of effect is typical of that of a tumor promoter. The finding that the same proportion of small cell and epidermoid lung cancers occurs in smoking and nonsmoking uranium miners also suggests that smoking has a promoting or cocarcinogenic effect. These findings have significance for the nonmining population. The average annual radiation dose to the lungs from natural sources (ie, burning of fossil fuels, presence of ^{210}Pb and ^{210}Po in tobacco smoke) is 250.5 millirems (rem = roentgen-equivalent-man) for the general population. Thus, every smoker suffers the combined effects of radiation and smoking. (15 refs)

- 78-6050 Can Animal and In Vitro Studies Give New Relevant Answers to Questions Concerning the Mechanisms of Carcinogenesis?** (Eng) Brodsky, A. (Office of Standards Development, U.S. Nuclear Regulatory Commission, Washington, DC, 20555). *Health Phys* 35(3): 429-430; 1978.

Mammographic Screening for Human Breast Cancer? (Eng) Thlefsen, L. A. (Section Radiation and Tumor Biology, Dept. Radiology, Univ. Utah Medical Center, Salt Lake City, UT, 84132); Brown, J. M.; Carrano, A. V.; Nandi, S. *J Natl Cancer Inst* 61(6): 1537-1545; 1978.

This report of an ad hoc committee appointed by the National Cancer Task Force reviews current arguments surrounding the role of mammography in breast cancer development and recommends directions for future research using animal or in vitro models. Human carcinogenesis studies have shown that the risk of breast cancer from ionizing radiation is not diminished by dose fractionation and is highly age dependent, resulting in an excess risk of 7.5 cases/10⁶ women/rad for women <35. In rats, fractionation of a 500 R dose did not change the overall incidence of mammary tumors, but it increased adenocarcinoma incidence and decreased fibroadenoma incidence. Hormonal factors modify radiation-induced mammary cancer in rats, and postpubertal animals are at higher risk than prepubertal animals. On the basis of current knowledge of cell transformation mechanisms and the results of present study protocols, two specific areas of future research are suggested: the specific effects of radiation dose fractionation on the efficiency of cell transformation, and the relationship between DNA repair processes and transformation. The mammary fat pad transplantation techniques and established in vitro cellular transformation systems is suggested. No further animal studies aimed at quantifying the tumor risk per rad should be initiated at this time. (58 refs)

8-6051 Iatrogenic Carcinogenesis. (Hun) Schuler, D. (II. Gyermekklinika, Semmelweis Orvostudományi Egyetem, Budapest, Hungary). *Orv Hetil* 119(37): 2239-2243; 1978.

Ionizing radiation and drugs with carcinogenic, cocarcinogenic or immunosuppressive effects lead to iatrogenic carcinogenesis. These drugs include cyclophosphamide, busulfan, chlorambucil, melphalan, 6-azauridine, chlornaphazin, arsenicals, hydantoin derivatives, phenacetin, diethylstilbestrol, and 18-methylnorethisterone. (92 refs)

8-6052 Multiple Pathways of DNA Repair in Bacteria and Their Roles in Mutagenesis. (Eng) Smith, K. C. (Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305). *Photochem Photobiol* 28(2): 121-129; 1978.

Photoreactivation, excision repair, and postreplication repair of DNA in bacteria are reviewed in relation to mutagenesis, which appears to be the result of error-prone DNA repair. There is growing evidence that carcinogenesis is also the result of error-prone DNA repair. One pathway of postreplication repair has been shown to be blocked by postirradiation treatment with the protein synthesis inhibitor chloram-

phenicol (CAP), suggesting that protein synthesis is required after UV irradiation before this pathway can function. This pathway requires functional *uvrD*, *recB*, and *lexA* genes. UV-induced mutagenesis is blocked by postirradiation treatment with CAP, suggesting that the *uvrD*, *lexA*, and *recB* gene products are involved in mutagenic repair. The fact that UV-induced mutations are not observed in *lexA* strains seems to support the idea that the CAP-inhibitable pathway is the mutagenic pathway. An area of mutagenesis research that is currently receiving considerable attention is based on the concept that error-prone (mutagenic) repair is due to a new repair function (the so-called SOS repair system) that is induced by damage produced in DNA. Since UV-induced mutagenesis is prevented by a short postirradiation treatment with CAP, postirradiation protein synthesis is apparently required for the expression of UV-induced mutations. The *recA* and *lexA* strains are not UV mutable; therefore, *recA* + *lexA* + functions are probably essential for expressing this inducible error-prone repair function. (75 refs)

78-6053 Evaluation of DNA Damage and Repair in Mammalian Cells Exposed to Chemical Carcinogens. Methods Potentially Useful as Short Term Pre-screening Tests. (Eng) Brambilla, G. (Dept. Pharmacology, Univ. Genoa, Genoa, Italy); Cavanna, M.; Parodi, S. *Pharmacol Res Commun* 10(8): 693-717; 1978.

Autoradiographic techniques for detecting unscheduled incorporation of labeled nucleotides into mammalian DNA and techniques for detecting single-strand DNA breaks in alkali are discussed in relation to their ability to predict the oncogenic potential of chemical agents. Although potentially good indicators of carcinogenic risks in humans, carcinogenicity tests in rodents present problems related to possible species differences in the metabolic activation of procarcinogens. This method is also time-consuming and expensive. Mutagenicity tests such as the Ames assay provide rapid information, and a short-term test based on DNA damage-repair in mammalian cells would be a useful complementary test. Of the short-term tests, the evaluation of DNA damage in vivo by the alkaline elution technique may prove to be the method of choice. To confirm its predictive value, the test should be extended to the evaluation of several hundred carcinogenic and noncarcinogenic compounds of different chemical structures. (122 refs)

78-6054 A Re-evaluation of Evidence for Carcinogen-induced DNA "Repair" Synthesis. (Eng) Melzer, M. S. (2550 Kemper Road, Shaker Heights, OH, 44120). *Chem Biol Interact* 22(2/3): 359-363; 1978.

The argument that carcinogenesis involves primary attack on nuclear DNA in the crucial reaction of the transforming process is based mainly on studies concerning 'repair' or unscheduled DNA synthesis. If it can be demonstrated that

upon treatment with a carcinogen, there is additional DNA synthesis (increased incorporation of labeled thymidine into DNA) of a nonreplicative type, this would indicate that a lesion has been introduced into the DNA that was being repaired, suggesting direct carcinogen-DNA interaction as the crucial step in carcinogenesis. This study evaluates the evidence for such carcinogen-induced repair synthesis and suggests that some of it is distinctly flawed. In fact, some of the evidence could just as well be interpreted as evidence for carcinogen-induced replicative DNA synthesis, which would point up the fact that carcinogens, in their initial effect on target cells, induce increases in (or even initiation of) new replicative DNA synthesis and/or new mitosis. It is hoped that the points raised will stimulate further thinking among carcinogenesis researchers about possible alternative mechanisms of initial cellular attack by chemical carcinogens. (27 refs)

- 78-6055 DNA Repair and Mutagenesis in Mammalian Cells.** (Eng) Hart, R. W. (Dept. Radiology, Ohio State Univ. Sch. Medicine, Columbus, OH, 43210); Hall, K. Y.; Daniel, F. B. *Photochem Photobiol* 28(2): 131-155; 1978.

Mammalian cell DNA repair is reviewed in relation to mutagenesis and carcinogenesis. Although DNA damage leads to measurable mutations in mammalian cells, the means by which this damage results in an inheritable change in base sequencing is not known. Depending on the type of insult and its location within the DNA, inheritable errors could arise during excision repair, DNA replication, or postreplication repair. Among the clinical syndromes associated with mutagenesis that have been studied most extensively are xeroderma pigmentosum (XP), dyskeratosis congenita, Fanconi's anemia, ataxia telangiectasia, and Werners, Bloom's, Chidiak-Higoshi, Hutchinson-Gilford, and Down's syndromes, all of which have a genetic predisposition to cancer and/or other specific syndrome anomalies. XP is characterized by hypersensitivity of the skin to solar radiation, a high incidence of multiple carcinomas, and deficiencies in DNA repair. The predisposition to cancer among XP patients is inversely proportional to their ability to repair UV radiation- and acetoxyacetylaminofluorene-induced damage. An explanation for the high frequency of mutation in XP variants, which are slow in postreplication repair but have normal excision repair, involves the possibility that the DNA polymerase III-like complex is altered, leading to the observed mutation frequencies. In bacterial systems, mutations in the gene for DNA polymerase III can lead to enhancement of spontaneous mutations in vivo. (326 refs)

- 78-6056 Glycopeptide Changes and Malignant Transformation: A Possible Role for Carbohydrate in Malignant Behavior.** (Eng) Warren, L. (Wistar Inst. Anatomy and Biology, 36th St. at Spruce, Philadelphia, PA,

19104); Buck, C. A.; Tuszyński, G. P. *Biochim Biophys Acta* 516(1): 97-127; 1978.

Studies comparing glycopeptides (GP) isolated from control and transformed animal cells are reviewed. Sephadex chromatography of Pronase-treated GP yields, among other fractions, groups A and B GP, which elute at mol wt approx 4,600 and 3,700, respectively; upon removal of the sugar, these peptides are reduced to a common size but retain a common substructure. After Pronase digestion, glycoproteins producing groups A and B GP have been found associated with nuclei, mitochondria, lysosomes and endoplasmic reticulum. Group A material is increased in malignant cells regardless of transforming agent or species of origin; it is strongly growth-dependent. Its presence has been related with tumorigenesis and noted both in vivo and in vitro. The total number of GP may be constant in normal and transformed cells, and as the number of group A GP increases, the number of group B GP decreases. Studies made of GP derived from individual glycoproteins of identical mol wt and isoelectric point from control and transformed cells. Among 24 different pairs of homologous glycoproteins, 20 differences of varying degrees of severity were noted. Apparently, the gross increase of group A GP seen upon Sephadex chromatography is the cumulative result of several changes in the carbohydrate components of many glycoproteins in crude fractions. It is hypothesized that these changes, particularly in the cell membrane, where most glycoprotein activity is found, do not endanger premalignant cells but alter their relationships with external factors and influences. This alteration could then lead to malignant change, perhaps by removing the cells' sensitivity to these external controlling factors. (188 refs)

- 78-6057 High Molecular Weight, Cell Surface-associated Glycoprotein (Fibronectin) Lost in Malignant Transformation.** (Eng) Vaheri, A. (Dept. Virology, Univ. Helsinki, 00290 Helsinki 29, Finland); Mosher, D. *Biochim Biophys Acta* 516(1): 1-25; 1978.

The literature on fibronectin (FBN), a polymorphic glycoprotein found in blood and tissues of vertebrates and in structures of adherent vertebrate cells, is reviewed, and the significance of its loss from surfaces of transformed cells in vivo and the relationship of FBN to the biology of cancer cells in vivo are discussed. Two forms of FBN have been identified: a high-mol wt, cell-surface-associated, transformation-sensitive form (I) and a high-mol-wt circulating form (II). Form I is decreased consistently in cells transformed by virus, including virus mutants temperature-sensitive for transformation. Cells from human glioblastomas, fibrosarcomas, rhabdomyosarcomas, and osteosarcomas produce FBN but have little form I FBN. Compared with normal parental cells, form I is also decreased in spontaneously and chemically transformed rodent cells. Among adenovirus-transformed embryo cells, there is a close correlation between a decrease in cells positive for FBN immunofluorescence at cell-cell con-

ect and an increase in tumorigenicity in syngeneic rats and mice. Although, there are exceptions, the conclusion that malignant cells may have a normal complement of surface-associated FBN seems premature when these exceptions are compared with well-characterized virally transformed or tumor-derived cells of genetically stable species. Transformation appears to be associated with alterations of FBN, sulfatoglycosaminoglycans, and collagen, but it is not known how these components interact in vivo and in vitro. A decreased association to matrix components by malignant cells may be crucial to unregulated growth. It is suggested that transformed cells have defective interactions and associations with matrix elements and thus are free to divide and move. Little is known of the role of form II FBN in neoplasia. Changes of this form are not common in patients with malignancies. (92 refs)

78-6058 Stress and Cancer: Fresh Perspectives. (Eng) Riley, V. (Pacific Northwest Res. Foundation, Seattle, WA, 98104). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1769-1776; 1978.

Studies of the relationship between stress and cancer are reviewed. According to epidemiological studies, religious groups such as Mormons and Seventh-Day Adventists have a reduced incidence of cancer even at anatomical sites not generally associated with the effects of smoking or alcohol consumption. This suggests the beneficial influences of a less stressful life-style upon pathological processes. Psychosocial screening questionnaires have been employed in an effort to correlate personality traits and cancer risk. A multihormonal approach for deciphering the effects of stress has led to the quantification and integration of the behavior of a broad spectrum of interrelated hormones associated with stressful events. The known interference of stress with immunocompetence appears to be the most promising rationale for the induction of disease by acute, chronic, or intermittent stress. Certain varieties of stress, however, suppress specific neoplastic processes rather than enhancing them. There is no explanation for this paradox. The enhancement of tumor growth or of tumor incidence by stress probably can only be observed in experimental circumstances in which the host exerts a total or partial controlling influence on the establishment or growth rate of the tumor. It is the disruption of such host control that permits stress to enhance pathological processes. (17 refs)

78-6059 Etiology of Cancer as Studied in the Platyfish-Swordtail System. (Eng) Anders, A. (Genetisches Institut der Justus-Liebig-Universität Giessen, Hein-

rich-Buff-Ring 58-62, D-6300 Giessen, W. Germany); Anders, F. *Biochim Biophys Acta* 516(1): 61-95; 1978.

Research in cancer etiology utilizing the platyfish-swordtail (Xiphophorus fish) tumor system is reviewed. Although inbreeding of wild-type populations produces only normal offspring, interspecific and interpopulational crossings produce progeny that spontaneously develop various neoplasms, including melanomas, pterinophoromas, neuroblastomas, thyroid carcinomas, kidney carcinomas, and reticulosarcomas. Genetic information coding for neoplastic transformation is represented by a "tumor gene" (Tu), which may be present in several copies on different chromosomes, including one copy on the terminal portion of the sex chromosome. Tu is normally repressed by cell-type-specific systems of regulating genes. Four types of neoplasm-triggering mechanisms have been recognized in this model, all mediated by Tu. These include altered cell differentiation, somatic mutation, germ line mutation, and hybrid crossings. However, neoplasms are usually initiated by a combination of tumor-inducing methods, and the ultimate type of cancer is always determined by the last step in the multistep process. The different cell stages of transformation in the melanophore system to melanoma have been well-characterized. Certain melanomas are preferentially located in certain compartments of the fish body, and 13 different genes governing 13 different compartments of melanoma expression are linked to the Tu. Likewise, the malignancy and benignancy of melanoma are apparently regulated by presence of the single gene R-Diff. Experiments on neoplasia etiology in this tumor system support generally accepted concepts for the origin of cancer and disclose relationships among the different concepts. (177 refs)

78-6060 Specificity of Arrest, Survival, and Growth of Selected Metastatic Variant Cell Lines. (Eng) Nicolson, G. L. (Dept. Developmental and Cell Biology, Univ. California, Irvine, CA, 92717); Brunson, K. W.; Fidler, I. J. *Cancer Res* 38(11, part 2): 4105-4111; 1978.

Animal tumor models for blood-borne metastasis that were developed by in vitro cloning or in vivo selection of malignant tumor cell populations to obtain organ-preferring variant tumor cell lines with altered arrest, survival, invasion, and growth properties are reviewed. Selection and some tumor cell characteristics of lung-, brain-, and ovary-colonizing metastatic B16 melanoma variants, liver-colonizing RAW117 lymphosarcoma variants, and lung-colonizing sarcoma variants are discussed. Cloning and fluctuation tests with the B16-F1 melanoma cell line and with a vasoformative sarcoma, MSV3T3-LN, demonstrated the presence of populations of high and low metastatic potential before in vivo selection, suggesting that each in vivo selection results in enrichment of more metastatic cells in each subsequent cell line established in culture. Organ preference in arrest and colonization may be explained by adhesive interactions of circulating tumor cells with noncirculating host cells in the target organ or by adhesive interactions leading to arrest in the mi-

circulation at specific locations. Tumor cell invasion appears to occur by a combination of mechanical and enzymatic mechanisms. In addition to unique tumor cell characteristics, host properties such as immune response can influence metastasis. Therefore, both tumor cell and host properties probably determine whether metastasis occurs in each tumor-host system. (48 refs)

- 78-6061 Cell Membrane Ionic Permeability, Calcium Ion, Mitochondria, and Carcinogenesis.** (Eng) Anghileri, L. J. (Department de Protection, Boite Postale No. 6, 92260 Fontenay-Aux-Roses, France). *Arch Geschwulstforsch* 48(6): 497-503; 1978.

Cumulative evidence in support of a hypothesis of carcinogenesis at the cellular level is reviewed. The hypothesis states that a carcinogen, chemical or viral, alters cell membrane permeability, which upsets the normal intracellular ionic composition of the cytoplasm and allows excess calcium ions to flow into the cell. Calcium is sequestered in the mitochondria, resulting in damage to its oxidative phosphorylation mechanism and also to its genetic component. Therefore, the cell will shift toward glycolytic means of energy production. Moreover, if released from damaged mitochondria into the cytoplasm, mitochondrial DNA may become incorporated into the nuclear genome and may induce malignant transformation. The role of mitochondrial DNA in the specification of membrane characteristics is also important. Damage to this function may lead to the loss of growth inhibition and communications with neighboring cells and effectors that is noted in transformed cells. (55 refs)

- 78-6062 Pathogenesis of Attic Cholesteatomas.** (Eng) Beales, P. (Royal Infirmary, Doncaster, England). *J R Soc Med* 71(10): 707-708; 1978.

The congenital, migration, and metaplasia theories of the pathogenesis of attic cholesteatomas (AC) are reviewed. Although the migration theory is the one most commonly accepted, the evidence of contact inhibition of stratified squamous epithelium and the absence of documentation of the evolution of AC from a preexisting perforation or from marginal perforations argue against this theory. The exact mechanism of AC formation is not known. (11 refs)

- 78-6063 Small Cell Carcinoma of the Lung: Cellular Origin and Relationship to Other Neoplasms.** (Eng) Tischler, A. S. (Dept. Pathology, Tufts Univ. Sch. Medicine, 126 Harrison Ave., Boston, MA, 02111). *Semin Oncol* 5(3): 244-252; 1978.

The origin and behavior of small cell carcinoma of the lung are considered in relation to its similarity to APUD (amine

precursor uptake and decarboxylation) cells. Cells from small cell carcinomas of the lung and from the more benign pulmonary carcinoid tumors contain secretory granules that are morphologically and, to some extent, cytochemically similar to those in normal pulmonary APUD cells. Both tumors produce amine and peptide hormones. Carcinoids have been observed in association with increased numbers of APUD cells that might represent hyperplasia or neoplasia in situ; such observations have not been documented for small cell carcinomas. Although small cell carcinomas have many similarities to carcinoid tumors and to normal pulmonary APUD cells, it cannot be stated that they arise from a specific cell type. Because the embryologic lineages of normal pulmonary APUD cells have not yet been determined with certainty, small cell carcinomas would have an unclear origin even if they had been observed histologically to arise from such cells. Some tumors that currently are classified as small cell carcinomas probably do not have APUD cell characteristics, but others appear to have both APUD and non-APUD features. A subclassification of small cell carcinomas based on a combination of physiological and morphological features might prove of prognostic and therapeutic value. (48 refs)

- 78-6064 Nasopharyngeal Carcinoma. Aetiological Aspects and Electronmicroscopic Observations.** (Eng) Prasad, U. (Dept. Otolaryngology, Univ. Malaya, Kuala Lumpur, Malaya). *J R Coll Surg Edinb* 23(2): 199-207; 1978.

Current knowledge of the etiology of nasopharyngeal carcinoma (NPC) is reviewed, and the results of an electron microscope study of 60 cases are presented. The study supports the view that NPC originates from squamous epithelial cells, and it indicates that, in addition to genetic factors, environmental factors play a significant role in the etiology of NPC. (48 refs)

- 78-6065 Metastatic Potential of Malignant Tumors.** (Eng) Carter, R. L. (Inst. Cancer Res., Sutton, England). *Invest Cell Pathol* 1(3): 275-286; 1978.

The metastatic potential (MP) of malignant tumors and contributing factors are reviewed based on clinical and experimental observations. Morphological factors include tumor site, size, and histology and the pattern of local tumor spread. This information can be supplemented by techniques such as immunoperoxidase staining to determine MP. However, more functional, nonmorphological features of the primary tumor are likely to be of greater importance. These features are the functional heterogeneity of tumor cells with respect to MP; the elaboration of certain tumor-associated products that may potentiate tumor spread; and immunological factors in the form of local host cell infiltrates in and around primary tumors. Tumor-associated products include substances that

originate largely or wholly from tumor cells and host cells. Tumor-specific antigens, ectopically produced hormones, and tumor angiogenesis factor may thus be contrasted with prostaglandins and collagenases. Irrespective of their cellular origin, however, both types of products contribute to MP. Thus, some host factors may act as determinants of metastasis, a view compatible with evidence that shows that host cells sometimes make up a far larger proportion of tumor populations than would be expected from conventional morphology. It is concluded that the MP of tumors cannot be assessed in terms of conventional tumor pathology alone. (122 refs)

6066 Constitutional Factors and Endometrial Carcinoma. (Eng) Lynch, H. T. (Dept. Preventive Medicine, Creighton Univ., Omaha, NB); Lynch, P. M. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 05-2117; 1978.

Several etiological factors in endometrial carcinoma (EMC) are identified by a review of the medical records of 154 EMC patients treated at one hospital from 1946 to 1965. The most common finding was obesity (123/154), which was massive in some patients. Other constitutional factors included hypertension (100/154) and diabetes mellitus (66/154). The combination of obesity, hypertension, and diabetes was seen in 46 women. A review of the literature indicated that nulliparity and late natural menopause are also risk factors for EMC. In an autopsy series of 30 patients who died from EMC revealed significant aberrations in pituitary, ovarian, pancreatic, and renal histology. Initial studies have not revealed any synergistic interaction between constitutional factors and exogenous estrogen. Multiple genotypes have been postulated to explain the occurrence of EMC in several familial cancer syndromes. It is suggested that the inherited gene(s) defect in certain instances of familial EMC may initially express itself in the endocrine system, possibly involving the pituitary-adrenal axes. Speculation that the adrenals might be the site of the inherited endocrine lesion is supported by statistical indications that adrenal estrogen production may have a heritable basis. (32 refs)

78-6067 An Overview of Hormone-associated Cancers. (Eng) Miller, A. B. (NCIC-Epidemiology Unit, Faculty Medicine, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Cancer Res* 38(11, part 2): 3985-3990; 1978.

Data on the etiology of hormone-associated cancers, particularly breast cancer, are reviewed. Although many breast cancer risk factors point to the relevance of hormonal factors, the findings are not uniform. If age at first pregnancy is the

prime epidemiological indicator of some largely internally influenced hormonal mechanism and if the risk ratio of approx 1.7 from the literature is appropriate, then the attributable risk (AR) for this factor is approx 25%. Family history of breast disease, with a risk ratio of 2.4, results in an AR of 20%. Finally, total fat intake, by a weighted average over pre- and postmenopausal women, results in an AR of 27%. The AR's for age at first pregnancy, which may be overestimated, and total fat intake, which may be underestimated are the most doubtful. There also may be an interaction between the two, and neither may adequately reflect the true risk factor. However, evidence points to the importance of dietary factors, and one study appears to confirm an association with high total fat intake. Dietary factors, although possibly mediated by a hormonal mechanism, may be found to play a major role in the etiology of breast cancer. Studies of endometrial and ovarian cancer also show the importance of hormonally associated factors, although not always the same way as for breast cancer. For both these cancers and for cancer of the prostate, dietary factors may also be relevant in their etiology. (47 refs)

78-6068 Genetic Factors in the Etiology of Breast Cancer. (Fre) Sancho-Garnier, H. (Departement de Statistique medicale, Institut Gustave-Roussy, 16 bis, avenue P.-V.-Couturier, F 94800 Villejuif, France); Henry-Amar, M.; Le, M. *Bull Cancer (Paris)* 65(2): 127-130; 1978.

Literature studies on the relationship of genetic factors to the development of breast cancer are reviewed. A higher risk is present for women with mothers or sisters with premenopausal breast cancer. Only a few studies have evaluated the incidence of breast cancer in twins but a concordance of 0.28 has been found for monozygotic twins vs 0.12 for dizygotic twins. The incidence of breast cancer in various ethnic groups changes upon migration, which indicates that environmental factors are involved. Attempts have been made to identify specific markers such as blood group, human leukocyte antigens (HLA), or fingerprints that may be associated with high-risk populations. An increased incidence has been found for young patients with type O blood and older patients with type A. The HLA haplotypes 2-12 and 10 have been found in families with tendency to develop breast cancer. One unconfirmed study relates cancer incidence to fingerprint characteristics. Apparently, families with breast cancer are more likely to be carriers of mammary tumor virus. As for many types of cancer, the development of breast cancer is probably due to a multigenetic transmission of susceptibility and to the action of environmental factors. (27 refs)

78-6069 Tumors of Dysgenetic Gonads in Females with Y Chromosome. (Pol) Boczkowski, K. (Samodzielna Pracownia Genetyki, Instytut Ginekologii i Poloznict-

wa AM, pl. Starynkiewicz 1, 02-015 Warsaw, Poland). *Postepy Hig Med Dosw* 32(3): 381-390; 1978.

Studies of the frequency, genetic basis, and origin of tumors of dysgenetic gonads in women with Y chromosomes are reviewed. Dysgerminoma of the left ovary was diagnosed in a 21-yr-old eunuchoid woman with a 46,XY karyotype. (31 refs)

78-6070 Chromosomes and Cancer. (Eng) Brown, J. K. (Radiation Biology Section, Australian Atomic Energy Commission, Private Mail Bag, Sutherland, New South Wales 2232, Australia). *Cancer Forum* 14: 97-100; 1978.

The origin of cancer may be due to a genetically unbalanced chromosome complement that predisposes a cell to malignant transformation. On the other hand, chromosome anomalies may be of a secondary nature, merely accompanying the more significant changes. Many, but not all, cancer cells have chromosome abnormalities. Clonal evolution is common in neoplasms, particularly leukemias. At present, only a few specific chromosome abnormalities characteristic of particular neoplasms have been found. (no refs)

78-6071 Hereditary Retinoblastoma: Delayed Mutation or Host Resistance? (Eng) Matsunaga, E. (Dept. Human Genetics, Natl. Inst. Genetics, 411 Mishima, Shizuoka-Ken, Japan). *Am J Hum Genet* 30(4): 406-424; 1978.

A review of 261 pedigrees with 2 or more cases of retinoblastoma taken from 11 different sources indicates that host resistance explains the variation in the expression of the retinoblastoma locus and that there is little need to postulate delayed mutation. Both penetrance and expressivity in the gene carrier can be defined as a variable determined by genetic and environmental factors, not by Poisson distribution of tumors formed. Of individuals who receive a new mutation from a healthy parent, approx 13% do not manifest retinoblastoma; the heritability of the host resistance is estimated at about 90%. Significant associations of human WBC antigens with retinoblastoma have been reported, and the cell-mediated immune response is thought to play a role in host resistance. The host resistance model suggests that nonhereditary retinoblastoma, due to somatic mutations, occurs in the most susceptible group of the general population, whereas unaffected carriers, including spontaneously regressed cases, are the most resistant group. Therefore, a genetic marker correlated with host resistance to retinoblastoma would be found with decreasing frequency in unaffected carriers, hereditary unilateral cases, the general population, and bilateral and nonhereditary cases. The detection of such a marker would be maximized by comparing unaffected carriers with nonhereditary cases. (36 refs)

78-6072 The Relation of Gene Control Mechanisms to Cancer. (Eng) Busch, H. (Dept. Pharmacology, Baylor Coll. Medicine, Houston, TX, 77030). *Z Krebsforsch* 92(2): 123-135; 1978.

Recent experiments on the involvement of genetic mechanisms in the cancer cell phenotype (growth and cell division, invasiveness, and metastasis) are reviewed. Support for the idea that gene control of cancer cells is aberrant emerges from studies that suggest that aberrations in gene control can be rectifiable. Combined teratoma cells and normal embryonic cells produced normal heterozygous guinea pig embryos. Normal controls produced in normal sequence in the biological clock were apparently capable of converting teratoma cells to normal cells. The direct controls of gene function are considered to be the nonhistone nuclear proteins. Studies showed that the nonhistone nuclear proteins of experimental hepatomas and nontumor tissues differ. In other studies, different antigens were found in the nuclear proteins of tumors and nontumor tissues. One was nuclear antigen NAg-1, the first fetal chromosomal protein. NAg-1 or No-Ag-2, a nucleolar protein, may be special stimuli that result in the transcription and translation of messenger RNA species for the cancer cell phenotype. There is uniform agreement that cancer cells exhibit characteristics that are uncontrolled by systems available to the host. However, it is possible that substances responsible for normal maturation at specific times of embryogenesis would function in tumor cells to reorder or eliminate the specific readouts related to the cancer process. Fetal readouts that may be responsible for the cancer phenotype are likely to be timing errors of dislocated genomic control which proper timing may be restored by the substances normally involved in this reordering process. (24 refs)

78-6073 Some Aspects of Human Tumor Genetics. (Rus) Pogosiants, E. E. (Oncological Res. Center, Moscow, USSR). *Vopr Onkol* 24(9): 15-24; 1978.

The role of genetic factors in cancer etiology is reviewed. In most human tumors, genetic effects are of little importance but environmental factors are of paramount importance. However, there are some rare tumors that are dependent on specific inherited genes. In some cases, genetic markers are responsible for the development of the tumor proper; in others, they are responsible for the complex syndromes in which a malignant tumor may be only one of the obligatory features. In other cases, a syndrome that predisposes to the development of tumors and/or leukemia is inherited. The recent discovery of the genetic heterogeneity of tumors at the same site (including common tumors such as breast and renal cancer) is of particular theoretical and clinical interest. (22 refs)

78-6074 Mendelian Genetics and Cancer. (Fre) Auer, J. L. (Service de Medecine A, Institut G.

ve-Roussy, 16 bis, avenue Paul-Vaillant-Couturier, F 94800
illejuif, France). *Bull Cancer (Paris)* 65(2): 131-136; 1978.

Approx 1,142 simple genetic patterns known to be associat-
ed with 2,336 syndromes, about 200 are associated with high
cancer risk. However, other factors such as the environment
may interact with these genes to affect cancer risk. It is some-
times difficult to distinguish between these factors. In
anconi's anemia and xeroderma pigmentosum, there is
predisposition to cancer development because of
chromosome instability. The role of the histocompati-
bility system in evolution of certain cancers is discussed.
The most common hereditary syndromes associated with
higher cancer risk are tabulated. (22 refs)

78-6075 **Malignant Neoplasms of Genetic Origin in
Drosophila melanogaster.** (Eng) Gateff, E. (Bi-
ologisches Institut I-Zoologie, Albert-Ludwigs-Universitat,
8 Freiburg im Breisgau, W. Germany). *Science* 200(4349):
1445-1451; 1978.

Malignant neoplasms that develop in recessive-lethal larval
mutants of *Drosophila melanogaster* are described. There are
x nonallelic mutants that develop malignant neuroblas-
tomas in the adult optic centers. These mutants, on chromo-
somes 1, 2, and 3, represent developmental genes that prevent
differentiation of the adult optic neuroblasts into adult optic
neurons by causing an uncontrolled, autonomous, invasive,
lethal, and transplantable growth of the adult optic neuro-
blasts and ganglion mother cells. Some neoplastic cells, even
though they are incapable of differentiation, retain parts of
their behavioral repertoire, whereas other neoplastic cells
become unresponsive to hormonal signals. Eight recess-
ive-lethal mutants develop imaginal disk neoplasms: five
form imaginal discs that grow in a compact, noninvasive fash-
ion, and three form neoplasms that grow in an invasive pat-
tern. Morphological variations exist among imaginal
disks from different mutant stocks, and neoplastic disks
in situ as well as after transplantation possess qualities
of both malignant and benign neoplasms. The presence
of *y f* clones on the integument indicates nonautonomy
and a capacity of the homozygous tumor cell for reversal
to the differentiating state; the absence of *y f* clones
shows autonomy and an incapacity for reversal. A third
type of tumor mutation induces malignant neoplastic
transformation of the presumptive blood cells in the
larval blood-forming organs (lymph glands). The mutant
genes are located on chromosomes 1, 2, and 3.
Plasmatocyte-type cells are the malignant component,
and they grow in an autonomous way; crystal cells do
not participate in the growth after transplantation. The
neoplastic state of the mutant blood cells in situ is not
autonomous, but may result from a normal factor else-
where in the animal. (54 refs)

78-6076 **Tumors Arising in Organ Transplant Reci-
pients.** (Eng) Penn, I. (Dept. Surgery, Univ.

Colorado Sch. Medicine, Denver, CO). *Adv Cancer Res* 28:
31-61; 1978.

The development of cancer in organ transplant patients is
reviewed. These patients can be classified into three groups:
(1) those with inadvertently transplanted neoplasms; (2)
those with cancer that arose de novo at some time after trans-
plantation; and (3) those with tumors present before graft-
ing. Data were collected on 65 patients who received organs
(1 heart, the rest kidneys) from donors who had cancer. Six
of the 13 organs from living donors contained neoplasms; one
of these tumors spread locally and one caused distant metas-
tases. Of the 52 cadaver organs, 20 contained cancer cells.
Five remained localized to the kidney, 1 spread locally, and
14 caused distant metastases that were histologically identical
to the original donor tumors. After transplantation, 5%-7%
of patients develop tumors arising de novo. The incidence is
100 times greater than that in the general population of the
same age range. Data are given for 548 recipients who devel-
oped 572 de novo tumors (24 patients had > 1 type of can-
cer). These tumors were not related to the 12 preexisting
recipient tumors treated from several weeks to 17 yr before
transplantation or to any of the 6 tumors found among the
650 donors. Of 164 patients who had tumors removed at the
time of or 5 yr prior to transplantation, 92 had no recurrence,
63 had a recurrence or metastases, 10 developed de novo
cancers, and 1 case remained unchanged. Cancer in organ
transplant recipients probably develops as a result of a com-
plex interplay of multiple factors, including alterations in im-
munity, immunosuppressive agents or other drugs, genetic
factors, and oncogenic viruses. (143 refs)

78-6077 **Tumor Immunity. An Overview.** (Eng) Siegel, B.
V. (Dept. Pathology, Univ. Oregon Health
Sciences Center, Portland, OR). *Am J Pathol* 93(2): 515-523;
1978.

From attempts to formulate specific modes of cancer therapy
based on the ability of the immune system to recognize and
destroy foreign antigens, it has become clear that tumorigene-
sis is affected by immunologic and nonimmunologic factors.
Tumors may evade immunosurveillance by a number of
mechanisms, including sneaking through, immunosuppres-
sion, antigenic modulation, serum blocking factor, antigen
shielding, genetic resistance, and immunostimulation. An
integral part of the immune response is the activation of mac-
rophages, possibly through interferon, to a specifically cyto-
toxic state, which may be associated with the prevention of
metastatic spread. Since much of the knowledge of im-
munologic mechanisms in tumor-cell killing has been gained
from in vitro experiments, the relevancy of such observations
to events in vivo remains unclear. However, tumor immunity
may be enhanced by (1) amplification of cytotoxic T cell
pathways; (2) modification of genetic restriction on immune
response to tumor antigens; and (3) use of immunopotential-
tators to stimulate macrophage cytotoxicity and phagocytic ac-
tivity. (37 refs)

- 78-6078 Acute Lymphocytic Leukemia Involving Pre-B Cells.** (Eng) Vogler, L. B. (Cellular Immunobiology Unit Tumor Inst., Dept. Pediatrics & Microbiology, Univ. Alabama, Birmingham, AL); Crist, W. M.; Cooper, M. D.; Lawton, A. R. In: *Human Lymphocyte Differentiation: Its Application to Cancer. Proceedings of the International Symposium on Human Lymphocyte Differentiation: Its Application to Cancer, held in Montpellier (France) by Institut National de la Sante et de la Recherche Medicale and Delegation Generale a la Recherche Scientifique et Technique, 2-4 March, 1978.* Serrou, B., Rosenfeld, C., eds. (Amsterdam: North Holland Publishing Company): 423 pp.; 407-413; 1978.

Some of the characteristics of precursor B cells (pre-B cells) are described, and their participation in the proportion of childhood acute lymphoblastic leukemias is discussed. Pre-B cells contain cytoplasmic IgM (cIgM+) but they appear to lack functional antigen receptors and detectable surface IgM (sIgM). Large pre-B cells in humans divide rapidly, giving rise to smaller pre-B cells that are the direct precursors of sIg+ B lymphocytes; they resemble the sIg- lymphocytes that are the precursors of B lymphocytes in mice. Generation of antibody diversity appears to begin at the pre-B cell stage of differentiation. Lymphoblasts from 4/22 children with acute lymphocytic leukemia had the pre-B phenotype. Cells from all four patients bore the D locus related p23,30 antigen; a proportion of cIgM+ lymphoblasts from patients 2 and 4 expressed barely detectable sIgM, and Fc receptors were present on virtually all cells from patients 1 and 2. In patient 2, cIgM+ blasts from a lymph node were devoid of sIgM, whereas 75% of cIgM+ blasts from bone marrow stained immunoglobulins were not found in any patient. Chemotherapy resulted in remissions associated with the disappearance of cIgM+sIg- lymphoblasts from the blood in all four patients. (27 refs)

- 78-6079 Macrophage Turnover and Traffic: A Review.** (Eng) Spector, W. G. (Dept. Pathology, St. Bartholomew's Hosp. Medical Coll., London, England). In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 15-18; 1977.

Current knowledge of the turnover rate of macrophages (MP) in different body states is reviewed. In steady-state conditions, the MP pool in sites such as the liver and peritoneum is maintained by a slow turnover of fresh MP from circulation and also by a process of mitotic division in situ. In inflammatory states, monocytes migrate to the site at a constant rate through interendothelial gaps in venules, and, once inside a lesion, they are converted to MP with enhanced phagocytic activity. Both processes probably depend on serum and humoral factors. Factors that accelerate monocyte release from marrow or initiate peritoneal MP mitosis in cell cultures have been discovered. Although there is a close correlation be-

tween hypersensitivity and chronic inflammation, it is not known whether MP mobilization is linked to T-lymphocyte activity. Complement, however, may be involved. MP occurs primarily by three mechanisms: endocytosis of foreign material, mitosis with lethal chromosome aberrations, or formation of multinucleate giant cells. Both resident steady-state populations and inflammatory MP are probably involved in carcinogenesis. (13 refs)

- 78-6080 Mononuclear Phagocytes and Antitumor Resistance: A Discussion.** (Eng) Keller, R. (Immunobiology Res. Group, Univ. Zurich, Schonleinstrasse 7, CH-8032 Zurich, Switzerland). In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 31-49; 1977.

The contribution of macrophages (MP) and MP-like cells to host tumor resistance is reviewed. The numerous effects of MP on tumor growth in vivo and in vitro are discussed. Mechanisms by which MP alter the growth of other cells are reviewed. MP activation by specific or nonspecific means. This activation, expressed as cytotoxic function, usually requires a latent period of 1-2 hr. An activated MP is capable of killing a variety of target cells (in vitro). This effect transcends intra- and interspecific compatibility barriers, and it is independent of the target cell type or growth characteristics. However, MP-mediated cytotoxicity shows some selectivity for transformed cells. The mechanism of MP-mediated cytotoxicity is not understood, but the process is resistant to x-rays and several metabolic inhibitors, requires energy, and possibly involves complement activation and proteases. In vivo studies have shown that passive transfer of activated MP can inhibit tumor growth, and research is underway regarding the in vivo modification of MP functions in the tumor-bearing host. Not only MP but also nonphagocytic peritoneal cells, phagocytic lymphoid cells, cytotoxic lymphoreticular cells, and natural killer cells have been implicated in antitumor resistance. (106 refs)

- 78-6081 The Influence of Tumour Cell Products on Macrophage Function In Vitro and In Vivo.** (Eng) James, K. (Dept. Surgery, Univ. Edinburgh Medical School, Teviot Place, Edinburgh EH8 9AG, Scotland). In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 225-246; 1977.

The effects of viable tumors, tumor culture supernatants, and tumor culture extracts on macrophage development and function are reviewed. Animal studies in vivo and in vitro have shown that accumulation of macrophages and their chemotactic responses can be impaired by tumors or their soluble products. Some findings indicate that tumors may

pair immunosurveillance against them or other tumors. Conversely, macrophage number, activity, or chemotaxis may be enhanced by tumors. In vitro studies have usually included that chemotactic response of human blood monocytes is depressed by tumors. However, the factors influencing macrophage function could also be of host cell or viral origin. The possible modes of tumor-macrophage interaction are manifold: tumor products could interfere with the production of factors that modulate macrophage function, prevent the necessary interaction of such factors, or tumor products themselves could have direct effects on macrophages. Normal macrophages may be sequestered at the tumor site and, therefore, rendered inactive, or tumor products may inhibit macrophage activity within a tumor. In any event, macrophage development and motility can be adversely affected, placing the host at a distinct disadvantage. (61 refs)

6082 Anti-tumour Effects of Macrophages Injected into Animals: A Review. (Eng) Den Otter, W. (Dept. Pathology, State Univ., Pasteurstraat 2, Utrecht, Netherlands); Dullens, H. F.; Van Loveren, H.; Pels, E. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 119-141; 1977.

Concerning cytotoxic macrophages, the local antitumor effect of macrophages injected into animals along with tumor cells, and the antitumor effect of macrophages injected at a distance from that of the tumor cells are reviewed. (67 refs)

6083 Cancer of the Large Bowel with Special Reference to Incidence and Etiology. (Eng) Baughn, B. B. (401 W. Main St., Frankfort, KY, 40601). *Am J Surg* 44(9): 548-553; 1978.

In addition to lung cancer, large bowel cancer (LBC) is the second most common cancer in the US, and it is much more common in people in the higher socioeconomic strata. This finding seems to be related to the fact that persons with diets high in fats and proteins also show an increased incidence of LBC. Three premalignant conditions are associated with LBC: adenomatous polyps, ulcerative colitis, and congenital multiple polyposis. Operative levels of carcinoembryonic antigen have been shown to correlate with the extent of the disease and prognosis for recurrence. (34 refs)

6084 Etiology and Pathogenesis of Tumors. (Rus) Diad'kova, A. M. (N. N. Petrov Oncological

Res. Inst., USSR Ministry Public Health, Leningrad, USSR). *Vopr Onkol* 24(9): 3-7; 1978.

Recent studies on the etiology and pathogenesis of tumors are reviewed with special regard to viral carcinogenesis. Penetration of the carcinogenic agent (virus, chemical substance, or radiation) into the body, primary reactions of the body to the agent, cellular changes, and the appearance or existence of conditions necessary for or facilitating tumor development are the basic steps of carcinogenesis. These steps can be interrelated and simultaneous, but none of them alone determines the fate of the cellular changes. Herpes virus type 2 and Epstein-Barr virus are suspected etiological agents in cervical carcinoma and Burkitt's lymphoma, respectively, in humans. (no refs)

78-6085 Pathogenesis of Malignant Neoplasms Induced in Hamsters by the Oncogenic DNA Simian Virus 40 (SV40). (Eng) Diamandopoulos, G. T. (Dept. Pathology, Harvard Medical Sch., Boston, MA, 02115). *Fed Proc* 37(7): 2082-2084; 1978.

Factors responsible for the morphogenesis of neoplasms induced in hamsters by simian virus 40 (SV40) were determined by inoculating random-bred Syrian golden hamsters with SV40 iv [$10^{6.5}$ median tissue culture infective dose ($TCID_{50}$)]. Six to 12 mo later, approx 90% of the hamsters developed lymphocytic leukemia, lymphoblastic lymphosarcoma, reticulum cell sarcoma, osteogenic sarcoma, and/or anaplastic sarcoma. Controls were tumor-free. Tumor antigen, tumor-specific transplantation antigen, and antibody to tumor antigen were found in the tumor-bearers. Similar results were obtained with three inbred hamster lines. Reticulum cell sarcoma cells lost their original morphology soon after dissociation into suspensions, but preserved their phagocytic activity throughout many in vitro passages. Osteogenic sarcoma cells lost both their differentiated phenotype and their capacity to form osteoid during serial passage. Both the lymphocytic and the lymphoblastic neoplastic cells preserved their lymphoid morphology and their ability to produce immunoglobulin after an indefinite number of in vitro passages. The effect of hamster age and virus dose on SV40-induced tumor development was studied. Random-bred 3-wk- to 12-mo-old hamsters received $10^{8.5}$ $TCID_{50}$ of SV40 iv, and groups of 3-wk-old hamsters were inoculated iv with SV40 aliquots of progressively decreasing titers. Tumor incidence and, to a lesser extent, tumor latency were directly dependent on the age of the animals at the time of virus exposure and on virus dose. The results suggested that cell replication at the time of oncogenic exposure enhances its susceptibility to transformation. Three strains of 3-wk-old inbred hamsters received $10^{7.5}$ $TCID_{50}$ iv, and tumor incidence and latency were approx the same in all three; however, random-bred hamsters were almost completely resistant under identical conditions. These results could be due to genetic differences, control at the cell-response level, or differences in immunological capacity. (15 refs)

- 78-6086 Virus Oncogenes and Carcinogenesis.** (Rus) Zhdanov, V. M. (D. I. Ivanovskii Inst. Virology, Acad. Medical Sciences USSR, Moscow, USSR); Al'tshtein, A. D. *Vopr Onkol* 24(9): 8-15; 1978.

Recent studies of viral oncogenes are reviewed with special regard to those of polyoma viruses, adenoviruses, and oncornaviruses. Each nondefective oncornavirus has three genes that are necessary for its reproduction: (1) *env*, coding for the precursor of the principal glycoprotein and low-mol-wt membrane proteins; (2) *pol*, coding for the synthesis of reverse transcriptase; and (3) *gag*, coding for the precursor of the internal structural proteins of the virion. Defective viruses are replicated by complementation with a helper virus. The simian virus 40 genome has only three genes: *A*, which codes for the nonstructural proteins synthesized before replication of virus DNA; *BC*, which codes for the synthesis of the main structural protein VP-1; and *D*, which codes for the synthesis of structural proteins VP-2 and VP-3. Most adenoviruses, including those that are not oncogenic in vivo, are able to transform cells in vitro. Virus-specific T and S antigens are always present in the adenovirus-transformed cells. These antigens appear to be coded by the adenovirus oncogene, and they are responsible for the cell transformation. The characteristics of the viral oncogenes suggest that they are cellular in origin. As a result of these studies, it is suggested that nonviral oncogenesis is due to a disturbance in the functioning of certain cellular genes, as a result of which they are transformed into endogenous oncogenes. (53 refs)

- 78-6087 The Gene Order of Avian RNA Tumor Viruses Derived from Biochemical Analyses of Deletion Mutants and Viral Recombinants.** (Eng) Wang, L. H. (Rockefeller Univ., New York, NY, 10021). *Annu Rev Microbiol* 32: 561-592; 1978.

The various experimental approaches that led to determination of the gene order of avian RNA tumor viruses are reviewed. Through biochemical analyses of deletion mutants and viral recombinants, the gene order 5'-gag-pol-env-src-c-3' can be drawn for sarcoma viruses and 5'-gag-pol-env-c-3' for leukosis and transformation-defective viruses. (180 refs)

- 78-6088 Bovine Leukemia Virus Involvement in Enzootic Bovine Leukosis.** (Eng) Burny, A. (Dept. Molecular Biology, Univ. Brussels, 1640-Rhode St-Genese, Brussels, Belgium); Bex, F.; Chantrenne, H.; Cleuter, Y.; Dekegel, D.; Ghysdael, J.; Kettmann, R.; Leclercq, M.; Leunen, J.; Mammerickx, M.; Portetelle, D. *Adv Cancer Res* 28: 251-311; 1978.

The major achievements of research over the last 20 yr on

the role of bovine leukemia virus (BLV) in enzootic bovine leukosis are reviewed. According to its high-mol-wt RNA-reverse transcriptase complex, structural proteins, their mode of maturation, and general morphology, BLV is considered a retrovirus belonging to the subgroup C mammalian oncornaviruses. However, this virus is unique in its way of budding, the strict Mg^{2+} requirement of its reverse transcriptase, and its property of inducing syncytia in monolayer cultures of nontransformed cells. In addition, neither molecular hybridization nor antigenic cross-reactivity occurs with any of the known RNA oncogenic viruses. BLV is an enzootic infectious agent. Persistent lymphocytosis (PL) is a clinical form of enzootic bovine leukosis—a percentage of lymphocytes are tumor cells containing BLV proviral DNA sequences. Infected animals actively synthesize antibodies to BLV, and there are several serologic methods of detecting BLV antibodies. BLV produced in culture can infect calves, sheep, goats, and chimpanzees, and it has induced tumors in PL in calves, sheep, and goats. Only a fraction of infected animals develop tumors. Virus dose, age at infection, and genetic make-up of the recipient appear important in determining the final outcome of the interaction between host and virus. (334 refs)

- 78-6089 Epstein-Barr Virus: The Ravager.** (Eng) Gross, R. (J. C. (Div. Otolaryngology, Albany Medical Center, Albany, NY, 12208); Parulekar, S. S.; Paonesu, D. F.; Rapoport, A.; Kouyoumgian, J. *Ann Otol Rhinol Laryngol* 87(5, part 1): 729-735; 1978.

The role of Epstein-Barr virus in infectious mononucleosis, Burkitt's lymphoma, and nasopharyngeal carcinoma is reviewed. (26 refs)

- 78-6090 Malignant Tumors Induced by Human Papilloma Virus.** (Pol) Jablonska, S. (Klinika Dermatologiczna AM, ul. Koszykowa 82a, 02-008 Warsaw, Poland); Orth, G.; Jarzabek-Chorzelska, M.; Rzeska, G.; Obal, S.; Glinski, W.; Favre, M.; Croissant, O. *Przegl Dermatol* 65(5): 497-507; 1978.

Studies of human papilloma viruses (HPV) are reviewed. HPV 3 induces both flat warts and a form of epidermodysplasia verruciformis (EV) characterized by lesions similar to flat warts. HPV 3 has slight, if any, oncogenic potential, but HPV 4, which also induces EV, is oncogenic. EV due to HPV 4 is characterized by very flat, reddish wartlike lesions, red plaques flush with the skin, hyperpigmentation reminiscent of pityriasis versicolor, and depigmentation. HPV 1, which induces plantar warts, and HPV 2, which induces common warts, do not seem to be oncogenic. Depressed cell-mediated immunity is of great significance in the dissemination and

istence of warts, especially flat warts, and EV. However, malignant transformation is due mainly to HPV 4. The possibility that specific vaccines can prevent transformation in patients with HPV-4 induced EV is discussed. (60 refs)

78-6091 The Human Papillomaviruses. (Eng) Orth, G. (Unite de Recherches sur l'etiologie virale des cancers humains, Laboratoire no. 147 associe au CNRS, 140 de l'INSERM, Institut Gustave-Roussy, 16 bis, rue P. Vaillant-Couturier, F 94800 Villejuif, France); Jansz, S.; Breitburd, F.; Favre, M.; Croissant, O. *Bull Cancer (Paris)* 65(2): 151-164; 1978.

Data on the properties and pathogenicity of human papillomaviruses (HPV's), the lesions induced by HPV's, in vivo virus-cell interactions, and factors involved in the production of carcinomas by papillomaviruses are reviewed. Recent biochemical and serological studies have shown the existence of at least four distinct types of HPV's that cause benign skin lesions. These viruses show hardly any antigenic relationships; their DNA's differ by their sensitivity to restriction endonucleases and show little, if any, sequence homology in molecular hybridization experiments using complementary DNA's transcribed in vitro. Data on the pathogenicity of HPV's are incomplete, but they indicate that some types of HPV's are preferentially associated with certain types of HPV. Epidermodysplasia verruciformis (EV) is associated with two types of HPV, HPV-3 and HPV-4. The lesions produced by these two viruses differ. Of a series of 13 EV patients, malignant transformation occurred in only 1/8 with HPV-3, which induces flat, wart-type lesions and hyperpigmented plaques. Intraepidermal or invasive carcinomas were observed in 5 patients infected with HPV-4, which produces reddish and pityriasis versicolor-like plaques. This suggests that at least one HPV may have oncogenic potential, as do rabbit (Shope) papillomavirus and bovine alimentary tract papillomavirus. (82 refs)

78-6092 Polyoma Virus, as a Model for Viral Skin Carcinogenesis. (Eng) Meyer, G. (Unite 119 de l'INSERM, 27 boulevard Lei-Roure, F 13009 Marseille, France). *Bull Cancer (Paris)* 65(2): 145-150; 1978.

Polyoma (Py) virus, the simplest model of transformation by DNA virus, is characterized along with Py virus-sensitive cells, virus/cell interactions, perpetuation of viral information, and the mechanism of Py virus-induced malignant transformation. Py virus is a small (45-m μ) DNA virus with icosahedral symmetry and without an envelope. Its capsid is composed of 72 capsomers forming an icosahedral structure. The virus contains a nucleic acid having a mol wt of 3.6×10^6

daltons, and the DNA is supercoiled. Three types of cells are sensitive to Py virus: cells that allow a complete virus cycle to take place, cells that do not allow maturation of infectious virions, and cells with intermediate properties. Three possible virus/cell interactions are reviewed: lytic infection, abortive infection, and malignant transformation. Perpetuation of viral information begins after penetration of viral DNA into the nucleus, with the production of early proteins (tumor and surface antigens), the induction of cellular DNA synthesis followed by viral DNA synthesis, the production of late proteins (virus antigen), and cell lysis. Nuclear and surface antigenic modifications are correlated with the mechanism of transformation in vitro and in vivo. (9 refs)

78-6093 Structural Organization of Papovavirus and Adenovirus DNA. (Rus) Roninson, I. B. (D. I. Ivanovskii Inst. Virology, Acad. Medical Sciences USSR, Moscow, USSR); Naroditskii, B. S. *Vopr Med Khim* 24(5): 579-591; 1978.

Studies of the structural organization and specific fragmentation of DNA in papova- and adenoviruses are reviewed with special regard to simian virus 40 and adenovirus 2. (142 refs.)

78-6094 Structure and Morphogenesis of Type-C Retroviruses. (Eng) Montelaro, R. C. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Bolognesi, D. P. *Adv Cancer Res* 28: 63-89; 1978.

Models for the structure and morphogenesis of avian and murine C-type retroviruses were derived from an extensive review of literature concerning retrovirus morphogenesis. The models are based on the molecular arrangement of virion structural components in the particle as well as on available data relating to the biosynthesis of these products. (128 refs)

78-6095 Herpes Simplex Virus Type 2 and Cervical Cancer. (Dut) te Velde, E. R. (Afdelingen Gynaecologie, Academisch Ziekenhuis, Utrecht, Netherlands); The, T. H. *Ned Tijdschr Geneesk* 122(33): 1226-1230; 1978.

Epidemiological and virological studies show a correlation between herpes simplex virus 2 (HSV-2) infection and carcinoma of the uterine cervix, which suggests that HSV-2 may be involved in the etiology of this carcinoma. (12 refs)

- 78-6096 Chemical-Viral Interactions in Carcinogenesis.** (Eng) Weinstein, I. B. (Inst. Cancer Research, Columbia Univ. Coll. Physicians and Surgeons, New York, NY). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1609-1620; 1978.

Studies on the possible role of RNA viruses in the transformation of epithelial cells by chemical carcinogens are reviewed. In 1972, it was discovered that cell cultures established from rat hepatomas induced by aromatic amine carcinogens synthesize RNA viruslike particles. Electron micrographs revealed that these included intracisternal A particles, enveloped A particles, and, more rarely, mature C particles. Almost all rodent cell cultures established from tumors induced by aromatic amine carcinogens, polycyclic aromatic hydrocarbons, or asbestos synthesized RNA viruslike particles, as did rat epithelial cell cultures transformed in vitro. All attempts to detect RNA viruses in human cancers were negative. Further studies indicated that viruslike particles associated with chemically induced rodent tumors lacked biologic activity. This result is consistent with studies indicating that although RNA viruslike particles or their biochemical markers can be demonstrated frequently in spontaneous and radiation- or chemically-induced rodent tumors, these particles only rarely induce neoplasia when introduced into normal animals. There is no direct evidence that virus activation plays a causal role in the induction of carcinoma in animals or humans by radiation or chemical carcinogens. The viruslike particles and virus-related sequences in spontaneous and chemical carcinogen-induced neoplasms may play the role of a cofactor in carcinogenesis. (30 refs)

- 78-6097 Recombinant Origins of Leukemogenic Murine Viruses (Parke-Davis Award Lecture, 1978).** (Eng) Lerner, R. A. (Dept. Cellular and Developmental Immunology, Res. Inst. Scripps Clinic, 10666 N. Torrey Pines Rd., La Jolla, CA, 92037). *Am J Pathol* 93(1): 9-26; 1978.

Four points concerning retroviral genes and their hosts are derived using data on murine systems, although much of the information can be generalized to other species, including primates. (1) Retroviral genes, as proviruses, comprise an extensive multigene family. (2) As with host genes, proviral expression is regulated during development and differentiation. (3) Members of the retroviral gene family are constructed out of functionally distinct modules. (4) Viruses with new or altered pathogenicity may be constructed from nonpathogenic members of the multigene family. The last point is the

most important. Within the infinite reassortment and recombination processes that occur by recombination, biologically distinct viruses with unique pathogenicity can be constructed. The generation of virion diversity is said to be by a somatic recombination of proviruses. What makes this concept more interesting is that the provirus encodes no differentiation molecules of the mouse. Thus, recombination not only generates virus but also alters differentiation molecules within the adult lifetime of the mouse. Neoplastic version is envisioned to take place within this framework; a somatic mechanism is responsible for changing the cell face in mice. (20 refs)

- 78-6098 Recent Studies on the Role of the Immune Response in Resistance to Virus-induced Leukemias and Lymphomas.** (Eng) Meruelo, D. (Dept. Pathology, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); McDevitt, H. O. *Semin Hematol* 15: 399-419; 1978.

The contributions of immunogenetics to the understanding of the influence of immune surveillance on neoplasia, particularly leukemias and lymphomas, are reviewed. The murine histocompatibility complex, *H-2*, plays a large role in the susceptibility and resistance of mice to virus-induced leukemia. The *H-2k/k* haplotype results in >90% incidence of leukemia in one crossed strain. *H-2*-linked immune response genes (involved in the immune response to virus, tumor-specific transplantation antigens) seem to be directly involved in conferring resistance to the development of malignancy. The *H-2* complex plays a major role in determining the specificity of T cells sensitized against a variety of antigens, including viruses, tumor-associated antigens, antigens induced by chemical modification of the cell surface, autoantigens, and non-*H-2* histocompatibility antigens. Two models have been proposed to explain the requirement for *H-2* compatibility in these cytotoxic T-cell responses. A product of the *H-2K* or *H-2D* region may interact with a virus or hapten on a cell membrane, resulting in a new antigen recognized by effector T cells, or the interaction of T cells with target cells, may involve a dual recognition system, with one needing an *H-2* gene product. A second immune response gene locus, separate from *Rgv-1*, may be responsible for conferring resistance specifically to Friend and radiation leukemia virus-induced neoplasia. Following intrathymic radiation inoculation, there is an increase in the cell-surface expression of *H-2K* and *H-2D* molecules on thymocytes of both susceptible and resistant mice, but *H-2D* molecules are increased a longer period of time in resistant mice. Immunogenetic studies have begun to make an impact on human disease, evidenced by the finding that children with acute lymphoblastic leukemia (ALL) expressing the *HL-A9* antigen had increased survival over other ALL patients. (127 refs)

CHEMICAL CARCINOGENESIS

6099 **The Need for a Mammalian Test System for Chemical Mutagens and Carcinogens** (Meeting abstract). (Eng) Stich, H. F. (Environmental Carcinogenesis Unit, British Columbia Cancer Res. Centre, Vancouver, B. C., Canada); Wei, L.; Whiting, R. *Can J Genet Cytol* 20(3): 1-7; 1978. (no refs)

6100 **International Programme for the Evaluation of Short-Term Tests for Carcinogenicity.** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Nr. Macclesfield, Cheshire SK10 4TJ, England); de Serres, F. J. *Mutat Res* 54(2): 13-206; 1978.

An international collaborative study was initiated to evaluate 5 mutagenicity assay systems (prokaryotic, eukaryotic, andongenetic) for their ability to predict chemical carcinogenicity, using 42 reference carcinogens and noncarcinogens. The response of each assay will be compared with carcinogenicity findings for each chemical, and divergences between individual assay results and carcinogenicity data will be viewed within the context of the response of other assays. (4 refs)

6101 **Organic Trace Analysis Using Direct Probe Sample Introduction and High Resolution Mass Spectrometry.** (Eng) Haddon, W. F. (Western Regional Res. Center, US Dept. Agriculture, Albany, CA, 94710). In: *Symposium on High Performance Mass Spectrometry: Chemical Applications held in Lincoln, November 3-5, 1976*. University of Nebraska, National Science Foundation, AEI Scientific, and INCOS Corp. 358 pp.; 97-119; 1978.

High-resolution selected ion monitoring measurements on samples introduced on a direct probe can provide accurate and highly specific qualitative and quantitative information about compounds present in trace amounts, even compounds of low volatility or chemical instability. Highest sensitivities are obtained for substances with large mass defects, such as halogenated pesticides and mycotoxins. (40 refs)

6102 **Analytical and Biological Analyses of Test Materials from the Synthetic Fuel Technologies. II. Extended Genetic and Biochemical Studies with Mutagenic Fractions.** (Eng) Rao, T. K. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Young, J. A.; Har-

degree, A. A.; Winton, W.; Epler, J. L. *Mutat Res* 54(2): 185-191; 1978.

Certain highly mutagenic fractions of the crude synthetic fuel Synfuel A-3 were subjected to extensive genetic and biochemical analyses. Slight (not more than two-fold) mutagenic activity was noted with all fractions when the *Salmonella typhimurium* strain that detects base-pair substitution (TA1535) was used; metabolic activation was required. Strains that detect frameshift mutations (TA1537, TA1538, and TA98) were more sensitive to the fractionated Synfuel. TA1538 and TA98 exhibited a 20- to 75-fold increase over the spontaneous mutation rate when metabolic activation with various induced rat liver microsomal fractions (S-9) was included. Qualitative differences were seen with different induced S-9 preparations, and rat liver enzymes were the rate-limiting factor in the activation of the highly active basic fraction. The data indicate that the mutagenicity of Synfuel A-3 occurs by a frameshift mechanism and that the fuel contains chemical mutagens requiring metabolic transformation for conversion into an active form. (12 refs)

78-6103 **High-Pressure Liquid Chromatographic Analysis of Arylhydroxylamines after Derivatization with Methyl Isocyanate.** (Eng) Sternson, L. A. (Dept. Pharmaceutical Chemistry, McCollum Labs., Univ. Kansas, Lawrence, KS, 66044); DeWitte, W. J.; Stevens, J. G. *J Chromatogr* 153(2): 481-488; 1978.

A method for the analysis of micromolar levels of arylhydroxylamines in liver homogenates is described. The arylhydroxylamine is extracted with dichloromethane and then converted to the corresponding N-hydroxyurea by reaction with methyl isocyanate prior to high-pressure liquid chromatographic separation. This procedure renders the reaction product stable in soln, and it converts the hydroxylamine to a species that can be distinguished from other amine metabolites and metabonates. (18 refs)

78-6104 **Further Evaluation of a Hamster Embryo Cell Carcinogenesis Bioassay.** (Eng) Pienta, R. J. (NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Pooley, J. A.; Leberherz, W. B. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group

for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1993-2011; 1978.

A standardized Syrian hamster embryo cell carcinogenesis bioassay was established, and results of its evaluation with 77 known carcinogens showed a high correlation (89%) with the reported carcinogenicities of these chemicals. No false-positive results were obtained with noncarcinogens, and spontaneous transformation was never observed in untreated cultures. However, until further evaluations are made, chemicals with negative responses cannot necessarily be considered noncarcinogenic. (11 refs)

- 78-6105 Mutagenicity of Ozonated, Recycled Water.** (Eng) Gruener, N. (Gulf South Res. Inst., New Orleans, LA, 70186). *Bull Environ Contam Toxicol* 20(4): 522-526; 1978.

The mutagenicity of ozonated and nonozonated recycled water was tested in the *Salmonella*/microsome system. Recycled water was concentrated by low-pressure, low-temperature (37-38 C) distillation, and the recovery of organics [measured as total organic carbon (TOC)] in the concentrates was 95%. The mutagenicity of this concentrated water, containing 20-250 µg TOC/plate, was tested in *Salmonella typhimurium* strains TA100 and TA98 with and without microsomes. Results were negative at these levels; higher levels of TOC could not be tested because of toxicity. Water ozonated for 15 min contained 25% less organics and was mutagenic to both TA100 and TA98. Microsomal activation was not required in either strain but with strain TA98, the presence of rat liver microsomes resulted in an additional increase in the number of mutants. The specific mutants formed during ozonation were not identified. (8 refs)

- 78-6106 Rat Liver Microsome-mediated N-Demethylation and Mutagenicity of Azoxymethane.** (Eng) Campbell, R. L. (Procter and Gamble Co., Miami Valley Labs., P.O. Box 39175, Cincinnati, OH, 45247); Supnick, J. D.; Hettrick, J. M.; Nigro, N. D. *Cancer Res* 38(12): 4585-4590; 1978.

The rat liver microsome-mediated metabolism of azoxymethane (AOM) to formaldehyde was studied in vitro. A mutagen reverting *Salmonella typhimurium* strains HisG46, TA1530, TA1535, and TA100 was detected in incubations of AOM (13.6 mM) with liver microsomes and NADPH. Mutagen production was dependent on the length of incubation and on microsomal protein and AOM concentration. Detection of the mutagen was most sensitive with strain TA100. The N-demethylation (N-DM) of AOM to formaldehyde by liver microsomes required NADPH and O₂, thus exhibiting mixed-function oxidase characteristics. Phenobarbital (80 mg/kg/day, 3 days) or 3-methylcholanthrene (40 mg/kg/day, 2 days) pretreatment of the rats did not significantly

alter the specific activity of microsomal AOM N-DM but it did increase microsomal cytochrome P-450 levels 164% and 40%, respectively. Cobaltous chloride (60 mg/sc) reduced AOM N-DM by 49% and cytochrome P-450 69%. SKF-525A in vitro inhibited AOM N-DM (43% in activity at 3 mM), but 7,8-benzoflavone did not. Disulfiram reduced microsomal AOM N-DM by 70% when given 0.25% (wt/wt) in the diet, but it did not alter cytochrome P-450 levels. The specific activity of microsomal AOM N-DM was 86% greater when animals were fed a rat chow diet than when they were fed a semisynthetic diet containing 56% dextrose, 25% casein, 7% salt mix, 5% corn oil, 5% bran, and 2% vitamin supplement. Compared with a semisynthetic diet control, AOM N-DM was increased 55% and 175%, respectively, in animals fed a semisynthetic diet or rat chow diet and then starved 18 hr. The addition of 30% beef fat, however, did not alter the level of AOM N-DM. Since beef fat enhances AOM intestinal carcinogenesis, the mechanism by which dietary fat enhances tumorigenesis may not be related to metabolism of the carcinogen but rather promotional factors. (28 refs)

- 78-6107 Inhibition of the Metabolism of the Colon Carcinogen, Azoxymethane, by Pyrazole.** (Eng) Fiala, E. S. (Naylor Dana Inst., American Health Foundation, Valhalla, NY, 10595); Kulakis, C.; Christiansen, C.; Weisburger, J. H. *Cancer Res* 38(12): 4515-4521; 1978.

To provide further evidence for the function of alcohol dehydrogenase in the metabolism of methylazoxymethane (MAM) and its precursor, azoxymethane (AOM), the effect of pyrazole (PZ), an inhibitor of this enzyme, on AOM metabolism were studied in vivo and in vitro. Male F344 rats treated with ¹⁴C-AOM (10.5 mg/kg, sc) alone (controls) exhaled approx 36% of the dose in 6 hr as ¹⁴CO₂, whereas rats pretreated with PZ (40 mg/kg, ip) exhaled approx 3.5%. Pretreatment of rats with 360 mg/kg PZ inhibited exhalation of ¹⁴CO₂ for at least 6 hr. After 48 hr, the amount of ¹⁴CO₂ exhaled comprised approx 50% of the dose in controls and 26% and 20% in the 40- and 360-mg/kg PZ-pretreated rats, respectively. Pretreatment with 40 mg/kg PZ increased urinary MAM levels 2.5-fold compared with controls; pretreatment with 360 mg/kg PZ increased the urinary AOM levels 2.5- to 3-fold. In contrast to controls and 40-mg/kg PZ-pretreated rats, 360-mg/kg PZ-pretreated animals showed increased urinary excretion of ¹⁴C-methylamine and continued ¹⁴C-MAM excretion during the 24- to 48-hr period after labeled AOM administration. Washed liver microsomes from PZ-treated rats converted AOM to MAM at the same rate as controls but the hydroxylation was inhibited by adding PZ to the incubation medium. These results show that PZ inhibits the metabolism of AOM by at least two steps. At 40 mg/kg, PZ inhibits MAM oxidation, presumably by blocking alcohol dehydrogenase. At 360 mg/kg, it blocks this reaction and inhibits the hydroxylation of AOM. (27 refs)

108 Failure of Ethyl Alcohol to Induce Dominant Lethal Mutations in Wistar Rats or to Synergize the Effect of X-rays in Swiss Mice (Meeting Abstract).

6109 Deuterium Isotope Effect in Bioactivation and Hepatotoxicity of Chloroform. (Eng) Pohl,

R. (Lab. Chemical Pharmacology, Natl. Heart, Lung, Blood Inst., Bethesda, MD, 20014); Krishna, G. *Sci* 23(10): 1067-1072; 1978.

details of the formation of phosgene (COCl_2) from chloroform (CHCl_3), including the electron transfer pathway and rate-determining step, were monitored by the use of the deuterium isotope. When unlabeled CHCl_3 was incubated with liver microsomes from male Sprague-Dawley rats given intraperitoneal injections of phenobarbital (80 mg/kg), COCl_2 was readily produced. This reaction was NADPH-dependent and was inhibited by carbon monoxide or SKF 525-A, which suggests that cytochrome P-450 catalyzed formation of COCl_2 . When deuterium-labeled chloroform (CDCl_3) was substituted for CHCl_3 , COCl_2 production was significantly curtailed; therefore, the cleavage of the C-H bond was the rate-determining step of the reaction. The hepatotoxicity of CDCl_3 and CHCl_3 (2.49 and 4.98 nanomoles/kg ip) was determined by measuring SGPT levels and by histologic examination. CDCl_3 was less hepatotoxic than CHCl_3 , producing only minor histological changes (as opposed to highly elevated levels). These findings implicate the oxidative dechlorination mechanism in the bioactivation and subsequent carcinogenicity of chloroform. (29 refs)

6110 Carcinogenic Effects of Chronic Exposure to Very Low Levels of Toxic Substances. (Eng)

W. O. R. (Dept. Regius Professor Medicine, Radcliffe Infirmary, Oxford OX2 6HE, England). *Environ Health Perspect* 155-159; 1978.

The effects of chronic exposure to very low levels of carcinogens are examined from a statistical point of view. The results indicate that at low dose rates, the age distribution of extra tumors is independent of the dose rate and that the expected number of extra tumors is simply proportional to the dose rate. Because of statistical uncertainties in the differences between the numbers of tumors found in a control group and a treated group of animals, cancer risks $< 10\%$ cannot be accurately characterized. Because of this, much work has gone into the fitting of mathematical models. Although the results of the models in any particular case will depend on the details of the models they happen to fit, the qualitative conclusions reached would have been reached whatever class of

models had been fitted. Therefore, these conclusions are valid as a basis for legislation. (3 refs)

78-6111 Best-Estimate Low-Dose Extrapolation of Carcinogenicity Data. (Eng) Guess, H. A. (Environmental Biometry Branch, Natl. Inst. Environmental Health

Sciences, Research Triangle Park, NC, 27709); Crump, K. S. *Environ Health Perspect* 22: 149-152; 1978.

A low-dose extrapolation technique was developed for dichotomous data and used to analyze carcinogenicity data for vinyl chloride, dieldrin, 1,1,1-trichloro-2,2-bis-(p-chlorophenyl)ethane (DDT), dimethylnitrosamine, and ionizing radiation. The results suggest that when the very flat and the gradually sloping (linear or nearly linear) dose-response curves are considered together, it is extremely difficult on mathematical grounds to reject the hypothesis that the dose-response curve is nearly linear in the dose range corresponding to increased risks over a background of $\leq 10^{-6}$. These results have implications both for test design and for risk assessment. They suggest that if the hypothesis of a nearly linear dose-response curve in the low-dose range cannot be ruled out by assumption, then it seems questionable that it can be rejected by the data, even in cases in which it may be false. 78-6112 Interactions of Vinyl Chloride with Rat-Liver DNA In Vivo. (Eng) Green, T. (Imperial

Chemical Industries Ltd., Central Toxicology Lab., Alderley Park, Cheshire SK10 4TJ, England); Hathway, D. E. *Chem Biol Interact* 22(2/3): 211-224; 1978.

The reaction of vinyl chloride (VC) with liver DNA in Wistar rats and the reaction of chloroacetaldehyde (CAA) and calf thymus DNA were investigated. 9β -D-2'-Deoxyribofuranosylimidazo(2,1-i)purine (ethenodeoxyadenosine) and 1β -D-2'-deoxyribofuranosyl-1,2-dihydro-2-oxoimidazo(1,2-c)pyrimidine (ethenodeoxycytidine) were identified in the enzyme hydrolysates obtained (1) from calf thymus DNA that had been modified by chemical reaction with CAA and (2) from liver DNA prepared from rats that had been exposed *po* to VC in their drinking water (250 ppm) for approx 2 yr. Thus, VC-derived chloroethylene oxide and/or CAA behaved as a bifunctional alkylating agent toward deoxyadenosine and deoxycytidine residues of DNA. It is concluded that modification of the DNA structure by VC, through imidazo-cyclization of deoxyadenosine and deoxycytidine residues and through depurination of the resulting ethenodeoxyadenosine residues, is related to the mutagenicity of VC. The carcinogenicity of VC in animals and in humans and its mutagenic properties after biotransformation (by microsomal enzymes) into the active metabolites chloroethylene oxide and CAA, which show electrophilic reactivity toward DNA, would appear to conform with the

idea of a relationship between carcinogenesis and mutagenesis. (41 refs)

- 78-6114 **Report on Carcinogenesis Bioassay of 1,2-Dichloroethane (EDC).** (Eng) National Cancer Institute (U.S. Dept. Health, Education, and Welfare, NIH, NCI, Bethesda, MD, 20014). *Am Ind Hyg Assoc J* 39(11): A26-A30; 1978.

The halogenated solvent 1,2-dichloroethane (ethylene dichloride, or EDC) was administered to rats and mice for 78 weeks at time-weighted av dosages of 95 mg/kg/day (high dose) and 47 mg/kg/day (low dose) in a carcinogenesis bioassay. In male rats, EDC caused forestomach cancers, multiple hemangiosarcomas, and subcutaneous fibromas. In female rats, EDC induced mammary cancers, appearing in some high-dose animals as early as the 20th week. EDC also caused breast and uterine cancers in female mice and respiratory tract cancers in both male and female mice. (no refs)

- 78-6115 **Macromolecular Binding and Metabolism of the Carcinogen 1,2-Dibromoethane.** (Eng) Hill, D. L. (Kettering-Mayer Lab., Southern Res. Inst., 2000 Ninth Ave., S. Birmingham, AL, 35205); Shih, T. W.; Johnston, T. P.; Struck, R. F. *Cancer Res* 38(8): 2438-2442; 1978.

Biochemical mechanisms related to the activation and inactivation of the carcinogen 1,2-dibromoethane (1,2-DBE) were investigated. In rats inoculated ip with 1,2-¹⁴C-1,2-DBE [30.4 μ Ci; 4.2 micromoles (μ mol)]: 0.2 ml ethanol, measurable amounts of radioactivity became bound to protein, RNA, and DNA of all major tissues. For each macromolecules class, the largest amounts of bound radioactivity were in the liver and kidneys. Optimum conditions for the rat liver glutathione S-transferase that uses 1,2-DBE as a substrate were established. The pH optimum was 8.2, the Km for 1,2-DBE was 25 mM, and Vmax was 2.1 μ mol/min/g liver. Considerable enzyme activity was found in rat kidney; detectable activity was present in lung, testis, spleen, and heart. Enzymatic activity leading to the irreversible binding of radioactivity from ¹⁴C-1,2-DBE to proteins in the reaction system was present in rat liver microsomes. The activity was inducible by phenobarbital but not by benz[a]anthracene. NADPH was required for activity of both the noninduced and the induced reactions; MgCl₂ stimulated both reactions. Bromoacetaldehyde, a reactive compound probably involved in the irreversible binding, was identified as a metabolite formed in the reaction system.

Radioactivity from ¹⁴C-1,2-DBE also became bound to chromosomal proteins by a nonenzymatic chemical reaction. Enzymatic reaction leading to binding to macromolecules and/or the chemical binding reaction may be involved in biological activity of 1,2-DBE. (22 refs)

- 78-6117 **Preliminary Report on the Possible Use of Neuronal Tissue Culture in Carcinogenesis In Vitro.** (Eng) Boulos, B. M. (Sch. Public Health, Univ. Illinois Medical Center, Chicago, IL, 60680). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 2019-2028; 1978.

The in vitro effect of the food additive thiodipropionic acid (TDPA) on frog (*Rana pipiens*) spinal cord explants was investigated. The explants were taken from tadpoles at stages V and X, and incubated in a solution containing water and minimum essential medium (9:1). Six days later, addition of 10⁻³ μ M TDPA to the culture for 24 hr caused retraction of neuronal fibers. Addition of TDPA for 5 days caused growth and thickening of the fibers, a granular appearance, and a large number of fibroblasts. Lowering the TDPA concentration to 10⁻⁴ μ M caused increased thickening and lengthening of the fibers plus increased branching and granularity. At 10⁻¹ μ M, TDPA caused degeneration and neurite retraction. The neuronal cultures with TDPA required no addition of nutrients and showed growth up to 40-42 days. Control cultures were unable to grow without serum, and they grew for only 30-32 days with serum. The neuronal tissue culture system may prove useful in the in vitro identification of chemical carcinogens. (43 refs)

-6121 Caffeine Inhibition of Liquid-holding Recovery from Ultraviolet-induced Budding Delay in Yeast Cells. (Eng) Dawson, P. C. (Dept. Physics, Univ. Victoria, Victoria, British Columbia, Canada); Johnson, R. G.; Rodin, L. J. *Radiat Res* 74(1): 191-198; 1978.

Examination of liquid-holding recovery from UV-induced budding delay in yeast cells (*Saccharomyces cerevisiae*) indicated that addition of 20 mg/ml caffeine to the liquid-holding medium completely inhibited the reversal of budding delay. When liquid-holding in caffeine was followed by photoreactivation, the budding delay was greatly reduced. These findings suggest that caffeine interferes with the excision of pyrimidine dimers. -6123 Testicular Atrophy and Impaired Spermatogenesis in Rats Fed High Levels of the Methylxanthines Caffeine, Theobromine, or Theophylline. (Eng) Reinberger, M. A. (Div. Pathology, Bureau Foods, Food and Drug Admin., Washington, DC, 20204); Friedman, L.; Farber, T. M.; Moreland, F. M.; Peters, E. L.; Gilmore, C. E.; Huan, M. A. *J Environ Pathol Toxicol* 1(5): 669-688; 1978.

Studies were conducted to determine whether simultaneous administration of sodium nitrite and the methylxanthines caffeine

(CF), theobromine (TB), or theophylline (TP) would produce lesions similar to those seen in animals treated with other amines and sodium nitrite. Osborne-Mendel male rats (4-6 wk old) were given the methylxanthines at a dietary level of 0.5% for 14-75 wk with and without sodium nitrite (also at 0.5%). The compounds did not produce neoplastic or preneoplastic lesions, but severe bilateral testicular atrophy with aspermatogenesis or oligospermatogenesis occurred in 85%-100% of the rats fed CF and TB. The methylxanthines were fed to male Holtzman rats (4 wk old) at a dietary level of 0.5% for 19 wk to determine whether they would induce testicular atrophy in a second rat strain. The testicular effects were even more pronounced in these rats: CF and TB induced testicular injury in nearly all animals; TP induced severe testicular atrophy in 14% and mild to moderate atrophy in 71%, and it had no effect in only 15% of the rats. There was a significantly reduced number of mitotic cells in testes from the CF-treated group vs those from the TP-treated group. Plasma testosterone concentrations were significantly elevated in the TB group and somewhat elevated in the CF group; plasma cholesterol levels were significantly increased in the CF and TB groups. The toxic effect of CF and TB appeared to be specific for the germinal epithelium of the seminiferous tubules; the Leydig cells in many severely atrophied testes appeared to be hyperplastic. (29 refs)

78-6124 Modification of DNA by Aflatoxin B₁ Creates Alkali-labile Lesions in DNA at Positions of Guanine and Adenine. (Eng) D'Andrea, A. D. (Sidney Farber Cancer Inst., Harvard Medical Sch., 44 Binney St., Boston, MA, 02115); Haseltine, W. A. *Proc Natl Acad Sci USA* 75(9): 4120-4124; 1978.

Terminally labeled (³²P) DNA fragments of known sequence were used to study the base specificity of modification of DNA by aflatoxin B₁ (AFB₁). The DNA used was a 117- or 168-nucleotide-long DNA fragment that contained the control region, the operator and promoter sequences, of the *lac*-*ose* operon. The 168-nucleotide DNA was incubated with 300 μM AFB₁ in the presence of activating enzymes supplied by a crude rat liver extract. This incubation modified the DNA in such a way that subsequent treatment with 1 M piperidine for 30 min or 0.1 M NaOH for 15 min at 90 C resulted in cleavage of the DNA at sites corresponding to the position of guanine residues. The lengths of the cleavage products were the same as those produced by dimethyl sulfate in an alkali-induced reaction. The 117-nucleotide fragment was incubated with 300 μM AFB₁ in the presence of a normal mouse liver extract, and again all possible guanine residues were accessible to modification by AFB₁, but the rate for each individual guanine varied. When the 168-nucleotide fragment was incubated with a high concentration of AFB₁ (1 mM) in the presence of purified rat liver microsomes, deproteinized, and incubated with 1 M piperidine at 90 C, extensive cleavage of DNA was noted, not only at guanine but also adenine residues within the sequence. The DNA products following AFB₁ treatment were identical in length to those

pretreated with Me_2SO_4 , a result that suggests that similar mechanisms are involved in the piperidine cleavage of both. (26 refs)

- 78-6125 Urinary Excretion of Aflatoxin M_1 after Administration of Aflatoxin B_1 in Sucrose- or Starch-rich Diets.** (Eng) Wise, A. (Regional Mycotoxin Center, Univ. Isfahan, Isfahan, Iran); Suzangar, M.; Messripour, M.; Mohammadi, J. *Br J Nutr* 40(2): 397-401; 1978.

The urinary excretion of aflatoxin M_1 (AFM₁) was compared in two groups of male Sprague-Dawley rats fed a sucrose- or starch-rich diet for 200 days. The diets contained (g/kg): casein (250), corn oil (50), mineral mix (60), vitamin mix (10), and starch or sucrose (630). In addition, 2 mg/kg aflatoxin B_1 was added to the diet. Animals were sacrificed at 75, 145, or 200 days, and livers were examined microscopically. In the last week of life, urine was collected from each rat for 24 hr and analyzed for AFM₁. Although the food intake of both groups was similar, the excretion of AFM₁ ($\mu\text{g/kg/day}$) was significantly less in sucrose-fed rats (mean value: 1.7 vs 2.3 in starch-fed rats). The livers of sucrose-fed rats were a larger proportion of body weight (49.5 vs 39.1 g/kg), providing more available tissue for metabolism. Therefore, the excretion per gram of liver showed an even larger deficit in sucrose-fed rats, the mean value being 270 vs 560 $\mu\text{g/kg/g}$ liver/day. There was no histological difference between the two groups in the liver slices analyzed. It is suggested that sucrose decreases the activity of the drug-metabolizing enzyme. (14 refs)

- 78-6126 Antacids, Bile-Salts, and Colon Cancer (Letter to Editor).** (Eng) Nomura, A. (Japan-Hawaii Cancer Study, Kuakini Medical Center, Honolulu, HI 96817); Stemmermann, G. N.; Guber, G. A. *Lancet* 2(8093): 785; 1978.

Of 8,006 men examined from 1965 to 1968 in the Japan-Hawaii Cancer Study, 345 had had a gastrectomy for gastric or duodenal ulcer. Many of these patients were probably former users of antacids based on aluminum hydroxide. During follow-up, 4 gastrectomy and 94 nongastrectomy men were diagnosed with large bowel cancer. The data do not support the view that aluminum hydroxide increases the risk for colorectal cancer. (1 ref)

- 78-6127 Lung Carcinogenesis Induced by Inhaled High-fired Oxides of Beryllium and Plutonium.** (Eng) Sanders, C. L. (Pacific Northwest Lab., Richland, WA, 99352); Cannon, W. C.; Powers, G. J. *Health Phys* 35(2): 193-199; 1978.

The cocarcinogenicity of inhaled, submicron, high-fired

$^{239}\text{PuO}_2$ and beryllium oxide particles was investigated in 600 Wistar rats. The BeO was calcined at 1000 C and $^{239}\text{PuO}_2$ at 750 C. The ultrafilterability of $^{239}\text{PuO}_2$ was <0 , and it did not increase with time in water suspension. Female rats were exposed via nose only to BeO and $^{239}\text{PuO}_2$ aerosols for a single period of 30-180 min. There were 12 exposure groups: two unexposed control groups (128 rats); three groups exposed to $^{239}\text{PuO}_2$ only (184); three groups exposed to BeO only (184); and four groups exposed to both oxides (119). The amount of oxide in the lung was determined in 3-5 rats in each group 24 hr after the single exposure, it ranged from 1.0 to 91 μg for BeO and from 4 to 100 μg for $^{239}\text{PuO}_2$. No unexposed rat developed a lung tumor. Only one of the 184 rats exposed to BeO alone developed a tumor. Lung tumor incidences were 10% at an alveolar deposition of 5 nCi $^{239}\text{PuO}_2$, 37% at 45 nCi, and 58% at 180 nCi. Tumor incidences after exposure to both oxides were 15% at 7.6 nCi $^{239}\text{PuO}_2$ and 14 μg BeO, 37% at 76 nCi $^{239}\text{PuO}_2$ and 14 μg BeO, 12% at 3.8 nCi $^{239}\text{PuO}_2$ and 91 μg BeO, and 58% at 59 nCi $^{239}\text{PuO}_2$ and 91 μg BeO. The alveolar clearance of ^{239}Pu decreased and the translocation of the radionuclide to thoracic lymph nodes increased in rats previously exposed to BeO. It is concluded that previous exposure to the BeO did not significantly change the incidence of lung tumors induced by $^{239}\text{PuO}_2$, despite the effect of BeO on alveolar clearance. (12 refs)

- 78-6128 Mutagenicity of Metal Compounds (Meeting Abstract).** (Eng) Kanematsu, K. (Second Department of Oral Surgery, Gifu Dental Coll., Hosumi, Gifu-ken, Japan); Kada, T. *Mutat Res* 53(2): 207-208; 1978. (no refs)

- 78-6129 The Mutagenicity of Hexavalent Chromium Decreased by Microsomal Metabolism.** (Eng) Lofroth, G. (Wallenberg Lab., Univ. Stockholm, S-106 21 Stockholm, Sweden). *Naturwissenschaften* 65(4): 207-208; 1978.

The mutagenicity of hexavalent chromium for *Salmonella typhimurium* strains TA1978 and Ta92, as measured with the Ames plate-incorporation assay, was decreased by the action of a microsomal activation system containing NADPH. No increase occurred in the absence of the dinucleotide, indicating that it was the main factor contributing to Cr(VI) metabolism in the microsomal system. Oxidation and reduction states did not change when Cr(VI) and NADPH were mixed in aqueous soln, which implied that at least one additional factor in the microsomal system was necessary for the reaction. (8 refs)

- 78-6130 Metabolic Deactivation of Hexavalent Chromium Mutagenicity.** (Eng) Petrilli, F. L. (Inst. I

ne, Univ. Genoa, Via Pastore 1, 16132 Genoa, Italy); De
ora, S. *Mutat Res* 54(2): 139-147; 1978.

the mutagenicities of various hexavalent chromium compounds (sodium dichromate, potassium chromate, chromic acid, basic zinc chromate, and basic lead chromate) for *Salmonella typhimurium* were tested in the presence of rat tissue preparations and human blood components. All hexavalent chromium compounds were weakly mutagenic for *S. typhimurium* his₅ strains and were more mutagenic for strain A100. Addition of the microsomal fraction from rat liver, human RBC lysates, or, to a lesser extent, the S-9 fraction from rat lung reduced the mutagenicity of all divalent chromium compounds. Human serum or plasma and the microsomal fraction from rat muscle had no effect on the mutagenicities of these compounds. In the presence of the microsomal fraction from rat liver or human RBC lysates, the addition of ascorbic acid, Na₂SO₃, reduced glutathione, ADH, or NADPH prevented hexavalent chromium mutagenicity, whereas KMnO₄ slightly increased it. The data could be relevant to the elective localization of chromium-induced human lung tumors and could account for the results of animal carcinogenicity tests, which generally show the development of tumors only at implant sites. (24 refs)

-6131 **A Study of Cancer in Chromate Production Workers.** (Eng) Hayes, R. B. (Johns Hopkins University, Baltimore, MD). *Diss Abstr Int B* 39(5): 37-2238; 1978. (no refs)

-6132 **Studies on the Mutagenic Properties of Bleaching Effluents.** (Eng) Ander, P. (Dept. Chemistry, Box 5604, Swedish Forest Products Res. Lab., S-114 86 Stockholm, Sweden); Eriksson, K. E.; Kolar, M. C.; Kringstad, K.; Rannug, U.; Ramel, C. *Svensk Papperstidning* (14): 454-458; 1977.

samples of industrial effluents from the bleaching of softwood kraft pulps were taken from six mills and tested for mutagenicity using a streptomycin-dependent strain (Sd-4) of *Escherichia coli* and different histidine-requiring mutant strains (TA1535, TA1537, TA1538, TA100) of *Salmonella typhimurium*. None of the effluents exhibited any significant mutagenic effects or toxicity toward *E. coli*. However, effluents from the chlorination (C) stages exhibited definite mutagenic effects on TA1535 and TA100; concentrated C-stage effluents also had a mutagenic effect on TA1537. A weak mutagenic effect was also produced by the hypochloride stage effluent, but the other effluents had little or no mutagenic activity. The addition of liver microsomes decreased the mutagenic activity of the C-stage effluent, indicating a metabolic detoxification of the mutagen(s). The mutagenic effects of the C-stage effluents were almost completely restricted to substances with low relative molecular mass. Part of the mutagenicity remained after ether extraction; the part that

was ether-soluble could be destroyed by alkali treatments. The C-stage effluents appear to contain compounds with alkylating and intercalating properties that lead to both base-substitution and frame-shift mutations. (6 refs)

78-6133 **Sarcoma at the Injection Site of Gold Sodium Thiomalate.** (Eng) Payne, B. J. (Dept. Pathology and Toxicology, Smith Kline & French Labs., Philadelphia, PA). *Vet Pathol* 15(Suppl 5): 39-50; 1978.

The local effects on rats following injections of gold sodium thiomalate were studied. Groups of 10 male and 10 female rats were injected in the rear legs with 3, 6, 9, 12, 24, 48, 96, or 192 mg/kg/day, with the right and left legs being injected alternately, every other day. The three highest doses were injected undiluted, the others were diluted with water to make a 2.5% soln. Doses of 48 mg/kg or more produced a considerable local reaction and rats became increasingly belligerent; therefore, rats in dose groups 192, 96, and 48 mg/kg were sacrificed on days 57, 112, and 212, respectively. No tumors were seen in these animals. Doses of 24 mg/kg were generally tolerated without local swelling, although two rats developed hematomas at 7 and 9 mo. Upon sacrifice of the remaining rats of this group (at 357 days) and of the other lower-dose groups (at 514-748 days), a total of nine fibrosarcomas and one rhabdomyosarcoma were found. Unlike the fibrosarcomas, the rhabdomyosarcoma did not invade surrounding muscle. Morphologically, the tumors resembled those found in other studies of the injection of heavy metals into rats. It is suggested that gold be added to the list of heavy metals that produce sarcomas in rats. (10 refs)

78-6134 **Mutagenic, Potentiating and Antimutagenic Activity of Certain Metallic Ions in the Rice Genetic System (Letter to Editor).** (Eng) Reddy, T. P. (Dept. Genetics, Osmania Univ., Hyderabad 500 007, India); Vaidyanath, K. *Curr Sci (Bangalore)* 47(14): 513-515; 1978.

Sets of rice seeds were treated with one of nine metallic salts and/or γ-rays. Seven metals produced chlorophyll mutations in the following order of potency: Ba, Cd (both equal to γ-rays), Cu, Hg, Sr, Fe, and Pb. Mn and Ca were not mutagenic. Sequential treatments suggested that radiation- and metal-induced genetic lesions interacted synergistically in mutation induction. (18 refs)

78-6137 Manganese Toxicity and Mutagenesis in Two Blue-Green Algae. (Eng) Singh, S. P. (Dept. Botany, Banaras Hindu Univ., Varanasi 221005, India); Kashyap, A. K. *Environ Exp Bot* 18(1): 47-53; 1978.

The toxicity and mutagenicity of manganese were examined in the coccoid blue-green alga *Chroococcus limneticus* and the filamentous blue-green alga *Plectonema boryanum*. *C. limneticus* responded slowly to $MnCl_2$ concentrations < 6 mM; at higher concentrations, the survival pattern declined exponentially. Only 1.6% of the cells could form colonies on nutrient agar in the presence of 0.01 M Mn. However, doses causing $< 50\%$ lethality (6 mM) were the most efficient at inducing the formation of abnormal cells. Higher doses were more lethal than teratogenic, although all survivors of 9 and 10 mM had abnormalities. The induction of phage- and streptomycin-resistant mutants of *P. boryanum* was investigated at $MnCl_2$ concentrations of 1.0×10^{-6} to 5.0×10^{-4} M. The resistant mutants arose 10-12 days after plating at frequencies ranging from 2.6 to 28.0×10^{-8} for phage resistance and 0.9 to 1.8×10^{-8} for streptomycin resistance. When the algae were exposed to graded concentrations of $MnCl_2$, a sigmoidal pattern of inactivation was observed. The streptomycin-resistant mutants showed increased sensitivity to $MnCl_2$ compared with those of phage-resistant and parent strains. In contrast to *C. limneticus*, microscopic observations revealed no abnormal cell formation or an increase in cell size. When the parent strain of *P. boryanum* was grown in the presence of low concentrations of $MnCl_2$, the phage-resistant mutants did vary in their sensitivity to Mn. The induced frequencies were concluded to be due to the induction of phage-resistant mutants. The max mutant frequencies were approx 10 times that of the background level. Streptomycin-resistant mutants were not induced to a significant level. (22 refs)

78-6138 In Vivo Mutagenesis Investigations of Four GRAS Chemicals (Meeting Abstract). (Eng) Jorgenson, T. A. (Stanford Res. Inst., Menlo Park, CA); Rushbrook, C. J.; Newell, G. W.; Green, S. *Mutat Res* 53(2): 205; 1978. (no refs)

78-6140 Chromosome Distribution Studies in Phenyl Mercury Acetate Exposed Subjects and Age-related Controls. (Eng) Verschaeve, L. (Laboratorium voor Antropogenetica, Vrije Universiteit Brussel, Brussels, Belgium); Kirsch-Volders, M.; Hens, L.; Susanne, C. *Mutat Res* 57(3): 335-347; 1978.

The distribution of metaphase chromosomes in the peripheral lymphocytes of 16 men exposed to phenyl mercury acetate was compared with that in 12 unexposed men. One hundred metaphases from both populations were trypsin-banded and karyotyped. The relative position of the metaphase chromosomes was studied by means of centromere-centromere distances (Δ^2) and centromere-metaphase center distances obtained by computer-aided mathematical transformation of the individual metaphase coordinates. Blood mercury levels were within normal limits in both groups: 0 to 3.5 $\mu g/l$ in the controls and 0 to 5.6 $\mu g/l$ in the exposed subjects. Cytogenetic analysis showed only a significant increase in hypodiploidy in the exposed subjects. There were no translocations. However, there were 18 significantly different Δ^2 values between the two groups. For 12 chromosome groups, the values were greater among the exposed subjects, and for 6 groups the values were smaller for the exposed subjects. Pair 1-1 was the only one for which the value in the exposed subjects was obviously smaller. The alterations in chromosome distribution due to phenyl mercury acetate were particularly evident among the D-group chromosomes. (18 refs)

78-6141 Nickel-induced Erythrocytosis: Efficacies of Nickel Compounds and Susceptibilities of Strains. (Eng) Hopfer, S. M. (Dept. Lab. Medicine, University of Connecticut Sch. Medicine, Farmington, CT, 06032); Siderman, F. W.; Fredrickson, T. N.; Morse, E. E. *Ann N Y Acad Sci* 306: 396-402; 1978.

Dusts of nickel subsulfide (αNi_3S_2), nickel sulfide (αNi_3S_2), nickel monosulfide (βNiS), amorphous NiS , and metallic nickel were administered to male Fischer-344 rats intrarenally (ir) to assess the relative efficacies of the compounds for erythrocytosis (EC) induction. The dusts, which were suspended in 0.2 ml glycerol diluted 1:1 with NaCl soln (0.9% mM), were injected into the right kidney. From 4 to 10 wk postinjection, significant differences were observed among the mean blood packed cell volume (PCV) values with the order being $\alpha Ni_3S_2 > \beta NiS > \alpha Ni_3S_2 > Ni > amorphous NiS$. Crystalline βNiS induced an EC that was almost equal to that for αNi_3S_2 , but amorphous NiS did not induce any EC. To study in vitro rates of dissolution of these compounds, blood samples from Fischer-344 rats were spun and equivalent amounts of Ni in the above compounds and solutions were incubated. Analyses were performed at 2, 3, 8, and 10 days after

ubation. After 10 days, the concentrations of dissolved Ni serum ($\mu\text{g-atom/ml}$) were 5.86 amorphous NiS, 3.50 αNi 1.53 $\alpha\text{Ni}_2\text{Se}_3$, 0.62 βNiS , and 0.38 Ni dust. Six male and female mice of the Fischer-344 (Group H), NIH Black (Group I), Wistar-Lewis (Group J), and Long-Evans (Group K) strains were injected with 5 mg $\alpha\text{Ni}_2\text{S}_3$ ir to study strain differences in EC induction. At 2 to 8 wk, significant differences in mean PCV were seen in the following hierarchy: Group H > I > J > K. At 4 wk postinjection, significant differences were seen in the mean reticulocyte count: Group H > I > K > J. It is suggested that induction of EC following injection could provide a screening technique to test the carcinogenicities of Ni compounds. (16 refs)

78-6142 Nickel and Strontium Distribution in Some Mouse Tissues; Passage Through Placenta and Mammary Glands. (Eng) Jacobsen, N. (Dept. Microbiology, Dental Faculty, Univ. Oslo, Blindern, Oslo 3, Norway); Alfheim, I.; Jonsen, J. *Res Commun Chem Pathol Pharmacol* 3(3): 571-584; 1978.

The distribution and retention patterns of nickel and strontium in the soft and hard tissues of female mice were studied. Isotopes of Sr (0.12 $\mu\text{g/g}$) and Ni (0.14 $\mu\text{g/g}$) were injected as the chlorides. The Sr concentration was comparable in the liver, kidney, and heart tissue, but brain tissue showed a concentration of one-eighth of those of the other soft tissues. The radioactivity in the calvaria and long bones was eight times greater than that in the liver, and the radioactivity in the lower incisors was two to five times greater than that in the bones. The distribution in fetal tissues was similar to that of the maternal tissue, but the concentrations were reduced. The concentrations in sucklings nursing from a nonradioactive female decreased more rapidly than those in sucklings nursing from the biological, radioactive mother. Ni was recovered in all soft tissues, the highest concentrations occurring in the kidney and brain, respectively. Ni had no apparent affinity for the mineralized tissues, and it was transferred through the placenta to the progeny; in many tissues, the progeny had higher concentrations of radioactivity than the mother. Ni was also transferred to sucklings through the mother's milk. The results indicate that Sr is a bone-seeking mineral that forms a hard tissue reservoir, whereas there is a prolonged retention of Ni in mineralized tissue. (16 refs)

78-6143 The Induction of Malignant Tumors in Rats by Nickel-containing Aerosols. (Rus) Saknyn, A. (Res. Inst. Vocational Hygiene and Occupational Diseases, Sverdlovsk, USSR); Blokhin, V. A. *Vopr Onkol* 24(4): 48; 1978.

The results of a toxicologic experiment on the long-term effects of nickel-containing industrial dusts (NCID) are presented. Random-bred albino rats were (1) subjected to daily inhalations of NCID (av content of dust in the chamber, 70

mg/m^3), 5 hr/day, 5x/wk, for 6 mo; (2) inoculated ip with NCID soln (90-150 $\text{mg}/1.5\text{ ml}$); or (3) administered NCID soln intratracheally (20-40 $\text{mg}/0.6\text{ ml}$). Within 6-15 mo of ip NCID administration, 6/39 rats developed sarcomas (3 reticulosarcomas of the abdominal lymph nodes, 3 fibrosarcomas of the abdominal wall). After ip and intratracheal administration of NCID, 1/5 and 1/26 rats, respectively, developed lung cancer. The latent period of lung tumor development in both cases was 17 mo. (12 refs)

78-6144 Evaluation of Tris (2,3-dibromopropyl)phosphate for Mutagenic and Transforming Activity in a Battery of Test Systems (Meeting Abstract). (Eng) Brunsick, D. (Dept. Genetics, Litton Bionetics, Inc., Kensington, MD, 20795); Matheson, D.; Bakshi, K. *Mutat Res* 53(2): 160; 1978. (no refs)

78-6145 Test of O,O-Dimethyl(1-hydroxy-2,2,2-trichloroethyl)phosphonate (Trichlorofon) for Carcinogenic Activity in Rats Following Oral (Esophageal-Gastric Intubation) and Intraperitoneal Application. (Rus) Teichmann, B. (Zentralinstitut für Krebsforschung, Akademie der Wissenschaften der DDR, Lindenberger Weg 80, DDR-1115 Berlin-Buch, E. Germany); Hauschild, F.; Eckelmann, A. *Arch Geschwulstforsch* 48(2): 112-119; 1978.

The carcinogenicity of O,O-dimethyl(1-hydroxy-2,2,2-trichloroethyl)phosphonate (Trichlorofon) was examined in albino rats following po (esophageal-gastric intubation: 22 mg/kg 2x/wk) and ip (12 mg/kg 2x/wk) administration. Controls were given po or ip NaCl soln. All animals were treated for 90 wk; the experiment was terminated at 118 wk. There was no statistically significant difference in tumor incidence between treated and control animals by either route of application. (41 refs)

78-6146 Selenium and Cancer: Effects of Selenium and of the Diet on the Genesis of Spontaneous Mammary Tumors in Virgin Inbred Female C₃H/St Mice. (Eng) Schrauzer, G. N. (Dept. Chemistry, Univ. California at San Diego, La Jolla, CA, 92093); White, D. A.; Schneider, C. J. *Bioinorg Chem* 8(5): 387-396; 1978.

The efficacy of dietary selenium in reducing the incidence of spontaneous mammary tumors was studied in inbred female C₃/St mice, which show an 80% to 100% incidence of spontaneous tumor development. The animals were maintained on a basal diet (main source of protein, fishmeal) containing 0.45 ppm Se. Se supplementation was started at 2 mo of age and continued throughout life. Mice receiving 0.1 and 0.5 ppm Se in the drinking water gained wt faster than those receiving no Se in the drinking water (controls) or those receiving 1.0 ppm; the difference was significant at 1 yr. After

24 mo, tumor incidence in the control group was 42%, which was significantly lower than that in mice fed a diet containing 0.15 ppm Se, with meat and dried skimmed milk as major source of protein (80%-100%, previous study). The incidence of tumors declined progressively and the age at first tumor appearance increased progressively with increasing Se supplementation. Tumor growth rates did not differ significantly among the groups. A higher frequency of mesentery tumors was observed among controls (5/7) than among Se-supplemented animals (3/14). There was no histological evidence of liver damage in any group. The data suggest that a human diet rich in Se-containing seafoods and cereals could lower the cancer risk compared with a predominantly meat-based diet. (9 refs)

78-6147 Mutagenicity of Heavy Metals (Meeting Abstract). (Eng) Deknudt, G. (Dept. Radiobiology, Lab. Genetics, S.C.K.-C.E.N., B-2400 Mol, Belgium). *Mutat Res* 53(2): 176; 1978. (no refs)

78-6148 Relation Between Gastric Cancer Mortality Rate and Amounts of Zn in Rice in Nara Prefecture, Japan. (Jpn) Ikeda, K. (Dept. Hygiene, Nara Medical Univ., Kashiwara-shi, Nara Prefecture 634, Japan). *J Nara Med Assoc* 28(6): 909-916; 1977.

The relationship between gastric cancer mortality and zinc levels in the rice was determined for Nara Prefecture, Japan. This region has the highest gastric cancer mortality rate in Japan, although the rate has been declining in recent years; in one of its districts (Uda), however, the rate has been rising in the elderly. Unhulled rice from 129 areas in Nara Prefecture was analyzed for trace metals. Zn, Fe, and Cu levels were higher than the av values for the nation, and that of Ca was lower. The coefficient of variation was higher for Fe, Cu, and Cd than for Mg, Zn, and Ca. The distribution curves for Mg, Ca, and Fe skewed to the left, that of Zn had two peaks. The ratio of the metal concentration in unhulled and hulled rice was 0.08 for Mg, 0.54 for Zn, and 0.90 for Ca. Classification according to district showed that Uda had higher levels of Mg, Zn, and Ca in its rice than the other districts. Apparently, the high level of Zn in rice is related to the high gastric mortality rate. (9 refs)

78-6149 Short-term Toxicity Study of Chocolate Brown HT in Pigs. (Eng) Hendy, R. J. (British Industrial Biological Res. Assoc., Woodmansterne Road, Carshalton, Surrey SM5 4DS, England); Butterworth, K. R.; Gaunt, I. F.; Hooson, J.; Grasso, P. *Toxicology* 11(2): 189-192; 1978.

The toxicity of Chocolate Brown HT a food coloring agent, was studied in 10-wk-old male and female Large White pigs. The coloring was incorporated in the diet for 13 wk at a dose

level of 0, 5, 20, or 100 mg/kg/day. There were no abnormalities in the condition or appearance of the pigs, body wt gain, absolute organ wts, or urine. Feces of pigs given 100 mg/kg/day were dark brown and occasionally maroon in color. Significantly reduced Hb concentrations in all groups of treated male and elevated WBC counts in a single female of a single male were not considered to be related to treatment with Chocolate Brown HT. Scattered significant differences in relative organ wts between control and treated pigs were also considered to be unrelated to Chocolate Brown HT. On the basis of these results, an acceptable daily intake of Chocolate Brown HT for man would be 1 mg/kg or about 70 mg for an adult. (6 refs)

78-6154 Correlation Between the Carcinogenicity of Organic Substances and Their Spectral Characteristics. (Eng) Veljkovic, V. (Boris Kidric Inst. Nuclear Sciences, Lab. Theoretical Physics, P.O. Box 522, 11001 Belgrade, Yugoslavia); Lalovic, D. I. *Experientia* 34(10): 1342-1343; 1978.

ce the UV radiation that is most effective in inducing can-
lies in the region 233-278 nanometers (nm), the UV ab-
sorption spectra of chemical carcinogens were analyzed to
determine whether they have peaks in this spectral region and
whether they differ in this respect from noncarcinogens. A
strong correlation was found between the UV spectral char-
acteristics and carcinogenicity of a variety of organic sub-
stances. The organic carcinogens had an absorption peak(s)
in the 206- to 248-nm region. These findings and those from
preceding work resulted in the formulation of the following
principle: if an organic chemical has an av quasi-valence
number < 3.20 and if its spectrum shows an absorption
peak(s) in the wavelength region 206-248 nm, it should be
considered carcinogenic. This rule was fulfilled for 91% of
chemicals tested. A mechanism of carcinogenesis is
proposed that assumes that cancer associated-DNA is a
blocked part of normal cell DNA. The most important step
in carcinogenesis is deblocking of cancer-associated DNA.
The deblocking mechanism is independent of the nature of
the carcinogenic agent and must be due to some characteristic
energy features. (6 refs)

78-6155 **Effects of Harman and Norharman on Spon-
taneous and Ultraviolet Light-induced Muta-
genesis in Cultured Chinese Hamster Cells.** (Eng) Chang, C.
(Dept. Human Development, Coll. Human Medicine, Mi-
chigan State Univ., East Lansing, MI, 48824); Castellazzi,
G.; Glover, T. W.; Trosko, J. E. *Cancer Res* 38(12):
27-4533; 1978.

The effects of nontoxic concentrations of two nonmutagenic
carboline derivatives, harman (HM) and norharman
(NH), on DNA repair and mutagenesis were studied in
cultured Chinese hamster (V79) cells. Cytotoxicity studies
showed that the colony-forming ability of the cells was unaf-
fected by 5 $\mu\text{g/ml}$ HM and decreased to only 85% by 10 $\mu\text{g/ml}$.
20 $\mu\text{g/ml}$ completely eliminated colony-forming ability,
whereas this dosage of NH inhibited plating efficiency to
only 65%. The survival of UV- or x-ray-damaged V79 cells
exposed to 30 or 50 μM HM was significantly reduced com-
pared with cells not treated with HM, and the effect was
concentration-dependent. The effect was not detectable at 10
 μM . The unscheduled DNA synthesis induced by UV light
(200-900 R) was slightly, but consistently, inhibited by HM,
but normal DNA synthesis was unaffected. The frequency
of spontaneous or UV light-induced ouabain-resistant or
thioguanine-resistant mutations was reduced by HM. The
effect of HM on survival and mutagenesis was greater than
that of NH and was detected primarily when cells were
exposed to HM immediately after UV irradiation. The muta-
tion frequency was reduced significantly by 28 μM NH at
3.5 days after UV irradiation and by 30 μM at 0-1.5 days
after irradiation. The data indicate that HM decreases the
capacity of V79 cells to repair DNA damage and fix muta-
tions, possibly because of its intercalation properties. (28 refs)

78-6156 **Perspective in Chronobiology of Air Pollution.**
(Eng) Stupfel, M. (French Natl. Inst. Health

(INSERM), 101 rue de Tolbiac, Paris 75013, France); Hal-
berg, F.; Mordelet-Dambrine, M.; Magnier, M. *Chronobi-
ologia* 4(4): 333-351; 1978.

Chronobiological experiments with rodents that determine
how cycles in air pollutant emissions synchronize, reinforce,
or interfere with the internal or endogenous rhythms charac-
teristic of human physiology or physiopathology are re-
viewed. (56 refs)

78-6157 **The Mutagenicity of a Dinitro-o-cresol-contain-
ing Pesticide.** (Hun) Nehez, M. (Kozegesz-
segugyi es Jarvanytani Intezet, SZOTE, Szeged, Hungary);
Selyes, A.; Paldy, A. *Egeszsegtudomány* 21(3): 237-243;
1978.

The mutagenicity of Krezonit E, which contains 50% dini-
tro-o-cresol (DNOC) as the active agent, was studied in vitro
in normal human WBC cultures and in vivo in bone marrow
cell cultures of treated male albino mice. The numbers of
human WBC with chromosome aberrations increased with
DNOC concentration, from 113/200 at 0.02 $\mu\text{g/ml}$ to
125/196 at 0.2 $\mu\text{g/ml}$ and to 129/200 at 2 $\mu\text{g/ml}$. Chroma-
tid-type aberrations accounted for 35.7% of all aberrations,
and their frequency was DNOC concentration-dependent;
chromosome-type aberrations accounted for 25%, and their
frequency was DNOC concentration-independent. Numerical
aberrations occurred at a frequency of 0.3%. The spon-
taneous aberration rate was 2.5%. In mice, the number of
cells with chromosome aberrations was (a) 75/100 in bone
marrow cultures from those treated with a single ip injection
of DNOC (20 mg/kg) and (b) 76-95/100 in those treated with
five ip injections of 1, 5, or 10 mg/kg on days 1, 3, 5, 7, and
9 before sacrifice on day 10, which indicates that the
mutagenicity of DNOC is higher after subacute treatment.
Most of the aberrations were of the chromosome type; labile
aberrations accounted for 4%-7%, stable aberrations for
68%-85%. Chromatid-type aberrations accounted for
1%-10%. The spontaneous aberration frequency was 1/100.
The findings show that DNOC is mutagenic. (24 refs)

- 78-6161 The Detection of Mutation in Human Diploid Fibroblasts after Mutagen Treatment Using Non-selective Cloning and Enzyme Electrophoresis.** (Eng) Nelson, R. L. (Dept. Surgery, Univ. Illinois Hosp., P.O. Box 6998, Chicago, IL, 60680); Harris, H. *Mutat Res* 50(2): 277-283; 1978.

Human diploid fibroblasts from a 21-yr-old man (RM3), an 11-yr-old boy (FS1), and a male infant (PM1) were exposed to ethyl methanesulfonate (EMS): 400-1,100 $\mu\text{g}/\text{ml}$ and examined for mutation using nonselective cloning and enzyme electrophoresis. RM3 cultures had three doses of EMS, and between each dose the cells were cultured in fresh medium. The RM3 cells maintained a normal morphology and a reasonable incidence of survivors with doses of EMS up to 1,100 $\mu\text{g}/\text{ml}$. PM1 cells, however, died at levels of EMS > 400 $\mu\text{g}/\text{ml}$. The FS1 culture was intermediate in its sensitivity to EMS. Clones that were isolated following mutagen treatment were analyzed by starch-gel electrophoresis. Two mutants were identified: an electrophoretic variant of peptidase D (PEPD) was observed in an FS1 clone and a phenotypic alteration involving phosphoglucosyltransferase (PGM₁) was found in an RM3 clone. (8 refs)

- 78-6162 The Evaluation of Sixteen Carcinogens in the Rat Using the Micronucleus Test.** (Eng) Trzos, R. J. (Upjohn Co., 301 Henrietta St., Kalamazoo, MI, 49001); Petzold, G. L.; Brunden, M. N.; Swenberg, J. A. *Mutat Res* 58(1): 79-86; 1978.

The ability of the micronucleus test to detect clastogenic promutagens/procarcinogens was evaluated using 16 known carcinogens, 15 of which require tissue-specific metabolic activation. Groups of three male TUC(SD) spf (Sprague-Dawley) rats were administered a single ip injection of one of three doses/compound. The direct-acting mutagen ethyl methanesulfonate and the promutagens/procarcinogens cyclophosphamide and 4-nitroquinoline 1-oxide produced statistically significant dose-response increases in the number of micronucleated polychromatic RBC (MP-RBC). A marginally significant dose response was exhibited by dimethylnitrosamine. Aflatoxin B₁ significantly increased the number of MP-RBC at two doses, but a dose-response relationship was not found. The other agents, 2-acetylaminofluorene, 4-aminobiphenyl, benzidine, diethylnitrosamine, 9,10-dimethylbenzanthracene, 1,2-dimethylhydrazine, ethyl carbamate, β -naphthylamine, ethionine, hexametaphol, and metronidazole, did not increase the number of micronuclei significantly. Thus, the micronucleus test appears to lack the

sensitivity for detecting procarcinogen/promutagens that require tissue-specific metabolic activation or are rapidly inactivated. (22 refs)

- 78-6163 Mutagenicity of Some Environmental Chemicals in Salmonella Test Systems without Chromosomal Activation (Meeting Abstract).** (Eng) Adams, J. (Regional Science Teaching Center, Regional Staff Development Center, Graduate Sch., Notre Dame of Marbel C. Koronadal, South Cotabato 9708, Philippines). *Mutat Res* 53(2): 142-143; 1978. (no refs)

- 78-6164 Comparison of Toxicity and Mutagenicity of Butyl Methanesulfonate among Human Lymphoblast Lines.** (Eng) Slapikoff, S. A. (Dept. Biology, Tufts Univ., Medford, MA, 02155); Andon, B. M.; Thilly, W. *Mutat Res* 54(2): 193-196; 1978.

A comparison was made of the toxicity and mutagenicity of butyl methanesulfonate (BMS) among four diploid human lymphoblast lines: MIT-2, from a female mononucleosis patient; GM 130, from a normal man; MGL8B-2, a clone derivative of line MGL8 isolated from a normal man; and WI-L2, from a man with hereditary spherocytosis. Each line was exposed to 0-3 mM BMS for 24 hr. A period of ≥ 12 d was allowed for expression of the mutant phenotype, lack of hypoxanthine-guanine phosphoribosyltransferase activity. The mutant fraction was determined by soft-agar plating of the cultures in the presence and absence of 10 $\mu\text{g}/\text{ml}$ 6-thioguanine. BMS was toxic and mutagenic to lines MGL8B-2, MIT-2, and WI-L2, particularly to the latter two lines. In contrast, GM 130 cells demonstrated almost complete resistance to these effects of BMS, even at the highest concentration tested. Line GM 130 was also highly resistant to the toxic and mutagenic effects of methylnitrosourea and methyltrinitrosoguanidine, at concentrations highly toxic and mutagenic to line MIT-2. The reason(s) for the resistance of line GM 130 is not known. (9 refs)

- 78-6165 The Potential Carcinogenicity of Methyl Fluorosulphonate ($\text{CH}_3\text{OSO}_2\text{F}$; Magic Methyl).** (Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Anderson, D.; Styles, J. A. *Mutat Res* 51(2): 285-287; 1978.

The potential carcinogenicity of methyl fluorosulfonate (MFS) was evaluated in two short-term in vitro tests, the Salmonella reverse mutation assay and in a cell transformation assay. In the former, MFS was mutagenic to *Salmonella* strain TA1538 in a dose-dependent manner at concentrations up to 500 $\mu\text{g}/\text{plate}$ in the absence of a metabolizing system. It produced a max of 140 revertants/plate (vs 20/plate

control cultures). MFS resulted in 100% lethality of baby hamster kidney 21/C13 cells at a concentration of 2.5 $\mu\text{g/ml}$, dose that also induced a max of 900 transformants/ 10^6 survivors (vs 60/ 10^6 in control cultures). Both cell survival and transformation induction were dose-dependent. The chemical activity of MFS and the results of these assays are consistent with this compound being a possible carcinogen. However, if not all, chemical alkylating agents are probably capable of producing positive results in *in vitro* assays, and they may not all prove to be carcinogenic *in vivo*. (9 refs)

6168 **Asbestos Exposure and Related Neoplasia. The 28 Year Experience of a Major Urban Hospital.** (Eng) Hasan, F. M. (Div. Respiratory Sciences, Arizona Health Sciences Center, Univ. Arizona, Tucson, AZ, 85724); Ash, G.; Kazemi, H. *Am J Med* 65(4): 649-654; 1978.

Forty-nine asbestosis patients were seen at Massachusetts General Hospital between 1945 and 1972, 30 of whom also had cancer: 17 mesothelioma, 12 lung cancer (6 adenocarcinoma), and 1 prostate cancer. Only four asbestosis cases were diagnosed before 1960, and the diagnosis has been made with increasing frequency since then. Forty-eight patients had been exposed occupationally to asbestos, and 38 of these patients had a history of significant exposure in naval shipyards. One asbestosis patient with adenocarcinoma had no known history of exposure. The mean age of the patients was 67.7 yr, 45/49 were men, and only 4 were nonsmokers. In 37 patients, the exposure to asbestos was > 15 yr. Most patients with brief exposure had an associated neoplasm, and they presented with symptoms related to the tumor and not asbestosis. In 9/12 cancer patients who gave a history of exposure of < 5 yr, the neoplasm was mesothelioma. Unlike patients with uncomplicated asbestosis who often had worked with asbestos until the time of their illness, in patients with asbestos-related neoplasm there was a long interval between last exposure and emergence of symptoms. The mean latent period between onset of exposure and diagnosis of asbestos-related neoplasia was 26.3 yr. When pathologic data on 20 pa-

tients with autopsy studies were correlated with premortem roentgenologic changes, the latter seemed to underestimate the underlying disease. (26 refs)

78-6169 **Aryl Hydrocarbon Hydroxylase in Asbestos Workers.** (Eng) Naseem, S. M. (Channing Lab., Dept. Medicine, Harvard Medical Sch., 180 Longwood Ave., Boston, MA, 02115); Tishler, P. V.; Anderson, H. A.; Selikoff, I. J. *Am Rev Respir Dis* 118(4): 693-700; 1978.

The hypothesis that significant asbestos exposure may lead not only to long-term pulmonary accumulation of aromatic hydrocarbons, but also to increased inducibility (Ind) of aryl hydrocarbon hydroxylase (AHH) was tested by investigating lymphoblast AHH Ind in 47 asbestos workers (all men) and 31 control subjects (11 men, 20 women). Controls included 20 relatives of the exposed subjects, 12 of whom were spouses. Mean Ind [3-methylcholanthrene (3-mc)-dibenz(a,h)anthracene (DBA)-induced divided by basal enzyme activity] was significantly greater in the asbestos workers than in controls. The estimated change in the mean value of MC Ind was 0.88, that of DBA Ind 1.59. The increased Ind appeared to result almost exclusively from an increase in induced enzyme activity; there was little change in basal enzyme activity. Factors such as age, smoking status, year of first exposure, yield of lymphoblasts in culture, and blastogenesis rate (measured by incorporation of ^3H -thymidine into nucleic acid) had no effect on differences in AHH Ind ratios. The fact that spouses with potential household exposure did not have increased AHH Ind suggests that some minimal dose of asbestos is essential for this effect. Increased AHH Ind may bear some relation to the previously determined greatly increased risk (≥ 90 -fold) of bronchogenic carcinoma in asbestos workers who smoked cigarettes vs workers who did not smoke. (47 refs)

78-6170 **Cytogenetic Effects of the Gaseous Phase of Cigarette Smoke on Root-Tip Cells of *Allium sativum* L.** (Eng) Pandey, K. N. (T. H. Morgan Sch. Biological Sciences, Univ. Kentucky, Lexington, KY, 40506); Benner, J. F.; Sabharwal, P. S. *Environ Exp Bot* 18(1): 67-75; 1978.

The cytogenetic effects of the gaseous phase of cigarette smoke from five types of experimental cigarettes on the root tip cells of garlic, *Allium sativum* L., were determined. The root tips were exposed to 1, 2, 3, 4, 5, 10, 15, or 20 35-ml puffs of smoke at 7-min intervals. Chromosome abnormalities in the form of breakages (mostly fragments), bridges, lags, stickiness, and differential condensation were observed. Multinucleate cells, polyploid cells, and multipolar mitotic divisions were also noted. In general, the percentage of abnormalities increased when root tips were exposed to higher numbers of puffs. The mitotic index increased at low levels of smoke exposure, but it declined sharply at higher levels

of exposure. An analysis of variance indicated that the results were highly significant for cigarette types and exposure times with respect to the mitotic index as well as the total number of abnormally dividing cells. (24 refs)

- 78-6171 Analysis of a Tumor-inhibiting Fraction of Tobacco Smoke Condensate.** (Eng) Chamberlain, W. J. (Tobacco Lab., Science and Education Admin., Federal Reserve, U.S. Dept. Agriculture, P.O. Box 5677, Athens, GA, 30604); Snook, M. E.; Haebeler, A. F. *J Anal Toxicol* 2(4): 138-140; 1978.

A tumor-inhibiting fraction of cigarette smoke condensate containing ether-soluble neutrals was partially characterized by gel filtration and gas chromatography. In addition to solanesol, sterols, and other neutral oxygenated compounds such as acetophenones and fluorenones, this fraction contained 1,3-indandione, a compound new to cigarette smoke. (10 refs)

- 78-6172 A Comparison of Short Term Bioassay Results with Carcinogenicity of Experimental Cigarettes.** (Eng) Basrur, P. K. (Dept. Biomedical Sciences, Univ. Guelph, Guelph, Ontario, Canada); McClure, S.; Zilkey, B. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 2041-2048; 1978.

Four experimental cigarettes with known tumor induction potential in long-term tests were examined in two short-term bioassays, the *Salmonella typhimurium* mutagenicity assay and the mouse skin response test, and the results were compared. In the mutagenicity assay, rankings using condensates and smoke on a concentration basis were similar for the extremes, but the intermediate rankings were reversed. The mutagenicity ranks of condensate calculated on a per cigarette basis paralleled the total tumor potency trend established by long-term tests. The mutagenicity values obtained for fresh smoke on a per cigarette basis did not follow the same pattern. All of the tests, including the sebaceous gland suppression response in mouse skin with 10% condensates, detected the same cigarette as the most active. The epidermal hyperplasia response in mouse skin did not distinguish the extremes with either of the two concentrations of condensate (10% and 20%) used. It is concluded that the epidermal hyperplasia response, assumed to be a measure of the promoters in cigarette smoke, was not helpful in rating cigarettes whereas the sebaceous gland suppression response, which reflects the tumor initiator levels, and the mutagenicity response may be used as indices of biological insult correlated with the tumor-inducing potency of cigarettes. (8 refs)

- 78-6173 In Vitro Transformation of Hamster Embryo Cells by Betel Tobacco Extracts.** (Eng) Umehara, K. (Dept. Experimental Pathology, Cancer Inst., 1-3-3 Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Takama, S.; Fujie, S.; Matsushima, T.; Sugimura, T. *Toxicol* 2(4): 243-246; 1978.

The transforming effects of the ethanol and ethyl acetate extracts of betel tobacco on cryopreserved hamster embryo cells were studied. The ethanol extract induced one transformed colony at 100 $\mu\text{g/ml}$, and the ethyl acetate extract induced two transformed colonies at 5 $\mu\text{g/ml}$ and two colonies at 10 $\mu\text{g/ml}$. The positive results in this assay were significant, that no transformation was observed in control cultures. The ethyl acetate extract of betel tobacco may contain carcinogenic principle(s) of betel. (5 refs)

- 78-6174 Aryl Hydrocarbon Hydroxylase Induction in Human Lymphocytes and Sensitivity of Several Hematopoietic Parameters to Cigarette Smoking.** (Eng) Shultz, T. D. (Res. Section., Mountain States Tumor Inst., Boise, ID, 83702); Smith, C. E.; Steuart, C. D. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1677-1687; 1978.

Aryl hydrocarbon hydroxylase (AHH) activity was assayed in cultured lymphocytes obtained from 30 healthy smokers and 30 healthy nonsmokers. Total WBC, Hb, and hematocrit values were also compared for the smokers and nonsmokers. Smokers had significantly higher total WBC and Hb levels than nonsmokers; the hematocrit differences were not significant. Mean AHH activity was twice as high in smokers (0.058 unit) as in nonsmokers (0.029 unit). There was a negative correlation between the number of cigarettes consumed per day and the level of AHH induction. Arbitrary low, intermediate, and high subgroups within the smoker and nonsmoker populations suggested a trimodal distribution of absolute AHH levels, but the significance of this relationship could not be determined because of the small number of individuals in each subgroup. The lack of a correlation between the number of cigarettes consumed per day and AHH induction suggests that the latter is under genetic control rather than being a quantitative response to polycyclic hydrocarbons. (50 refs)

- 78-6175 Metabolic α -Hydroxylation of the Tobacco-Specific Carcinogen, N'-Nitrosornicotine.** (Eng) Chen, C. B. (Div. Environmental Carcinogenesis, National Cancer Inst. Disease Prevention, American Health Found., Bethesda, MD, 20892).

n, Valhalla, NY, 10595); Hecht, S. S.; Hoffmann, D. *Cancer Res* 38(11, part 1): 3639-3645; 1978.

The metabolism of N'-nitrosornicotine (NNN), a carcinogen that occurs in cigarette and cigar tobacco, mainstream and sidestream cigarette and cigar smoke, chewing tobacco, and snuff, was investigated in male F-344 rats, with emphasis on the α -hydroxylation pathway. Since α -hydroxynitrosamines are unstable, the model compounds 2'- and 5'-acetoxy-NNN were hydrolyzed to determine the decomposition products of 2'- and 5'-hydroxy-NNN. The major products of 2'-acetoxy-NNN were myosmine (MM: 50%-60%) and hydroxy-1-(3-pyridyl)-1-butanone (HPB: 5%-10%), that of 5'-acetoxy-NNN was 2-hydroxy-5-(3-pyridyl)-tetrahydrofuran (HPTHF: 60%-70%). Hydrolysis of a third model compound, 4-(N-carbethoxy-N-nitrosamino)-1-(3-pyridyl)-1-butanone, also gave HPB (50%-60%). These results support the intermediate role of electrophilic diazohydroxides and/or carbonium ions in the decomposition of 2'- and 5'-hydroxy-NNN. These electrophiles may be active forms of NNN, since all three model compounds were mutagenic toward *Salmonella typhimurium* TA100 without enzymatic activation. Upon incubation of ¹⁴C-NNN with rat liver microsomes, O₂, and NADPH, HPB and HPTHF were produced as the 2,4-dinitrophenylhydrazone derivatives. MM was formed in incubation mixtures analyzed without derivative formation. When rats were inoculated with 87.3 μ g ¹⁴C-NNN sc, 73%-85% of the dose appeared in the 48-hr urine. The major metabolites were 4-(3-pyridyl)-4-oxobutyric acid, 4-hydroxy-4-(3-pyridyl)butyric acid, and 5-(3-pyridyl)-tetrahydrofuran-2-one, the oxidation products of HPB and HPTHF. The results are consistent with the hypothesis that NNN is activated by α -hydroxylation. (36 refs)

78-6176 **Chemical Studies on Tobacco Smoke. II: Studies on Non-volatile Nitrosamines in Tobacco.** (Eng) Hecht, S. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, Dana Road, Valhalla, NY, 10595); Chen, C. B.; Dong, M.; Orna, R. M.; Hoffmann, D.; Iso, T. C. *Beitr Tabakforsch* 9(1): 1-6; 1977.

The isolation of the Z (syn) and E (anti) isomers of N'-nitrosornicotine (NNN) from tobacco, the influence of curing and stalk position on NNN levels in tobacco, and the synthesis of two new nitrosamines that may also be present in tobacco are described. Commercial and noncommercial (Burley, Bright) tobacco samples were used. The E/Z ratio in fine-cut chewing tobacco was determined by high-pressure liquid chromatography to be similar to that observed in solution at similar pH (7.6) and temperature (25 C). The interconversion rate was first-order and reversible, and it increased at lower pH. NNN was not detected (detection limit, 40 nanograms/g dry tobacco) in uncured tobacco. In tobacco grown in high N fertilization, the presence of NNN was confirmed beginning at the half-cured stage. NNN levels were higher in the high-N than in the low-N-fertilized samples, in which NNN was detected only after complete curing. No significant

correlation was observed between stalk position and NNN levels in one variety of Bright tobacco. 4-(N-methyl-N-nitrosamino)-1-(3-pyridyl)-butanal and 4-(N-methyl-N-nitrosamino)-1-(3-pyridyl)-1-butanone, two additional nitrosamines that, theoretically, could also arise from nicotine were synthesized, and a detailed description of the process is given. (21 refs)

78-6177 **Long-Term Fate of [¹⁴C]Nicotine in the Mouse: Retention in the Bronchi, Melanin-Containing Tissues and Urinary Bladder Wall.** (Eng) Szuts, T. (Dept. Toxicology, Univ. Uppsala, Biomedical Center, Box 573, S-751 23 Uppsala, Sweden); Olsson, S.; Lindquist, N. G.; Ullberg, S.; Pilotti, A.; Enzell, C. *Toxicology* 10(3): 207-220; 1978.

The long-term fate of N-methyl-¹⁴C- and 2'-¹⁴C-labeled nicotine in pigmented C57BL and albino NMRI mice was studied using whole-body autoradiography, liquid scintillation counting, and thin-layer chromatography (TLC). Thirty days after injection, N-methyl-¹⁴C-nicotine persisted in the pigmented uveal tract, respiratory mucosal lining, and urinary bladder wall of the pigmented mice. Late-gestation fetuses showed a high accumulation in the eye, inner ear, and respiratory tract. The distribution was similar in the albino mice, except that no accumulation was found in structures corresponding to the melanin-containing tissues of the pigmented mice. The activity levels in the bronchi decreased faster when 2'-¹⁴C-nicotine was used. Quantitative measurements of the retention of the two ¹⁴C-labeled nicotine preparations confirmed the autoradiographic findings. TLC studies showed that no nicotine was present in the lungs after 24 hr and that only unmetabolized nicotine was present in melanin after 4 hr. Some reactive nicotine metabolites may be responsible for the retention in the urinary bladder wall, which persisted even after rinsing. The accumulation and long-term retention of nicotine in melanin-containing structures might accelerate the development of drug-induced or senile changes in these tissues. An accumulatory mechanism might also participate in the pathogenesis of urinary bladder cancer. (23 refs)

78-6178 **Dietary Fibre and Experimental Colon Cancer (Letter to Editor).** (Eng) Heaton, K. W. (Dept. Medicine, Bristol Royal Infirmary, Bristol BS2 8HW, England); Williamson, R. C. *Lancet* 2(8093): 784-785; 1978.

The protective effect of bran against colon cancer induced by cycasin derivatives in rats, an effect not observed with a diet containing three times the ordinary amount of dietary fiber, may be due at least in part to its lower energy value. Bran-fed animals grew more slowly and, for most of the experiment, their body wt (and thus their carcinogen dose) was only half that of rats receiving the fiber-enriched chow. (11 refs)

78-6179 Protective Effect of Dietary Fibre Against Chemically Induced Bowel Tumours in Rats. (Eng) Fleiszer, D. (McGill Univ. Surgical Clinic and Dept. Pathology, Montreal General Hosp., Quebec, Canada); MacFarlane, J.; Murray, D.; Brown, R. A. *Lancet* 2(8089): 552-553; 1978.

The effects of different levels of dietary fiber (0-28 g/100 g diet) on stool production and on the incidence of dimethylhydrazine-induced (20 mg/kg/wk for 20 wk, sc) large intestinal carcinomas were studied using inbred male Chester Beatty rats. Stool mass and frequency decreased with decreasing dietary fiber, the differences in stool frequency and mass between the highest fiber level group and the other groups being statistically significant ($p < 0.05$). The incidence of colonic carcinoma increased with decreasing fiber content except that the rats given 5 g fiber/100 g diet had more carcinomas (70.6%) than the group given 0 g fiber/100 g diet (42.1%). The difference in carcinoma incidence between the group given the greatest amount of fiber (5.9%) and the other groups was significant. The results support the hypothesis that a diet with high fiber content leads to frequent, bulky stools and a reduced incidence of colonic cancer. (14 refs)

78-6180 Dietary Fibre and Experimental Colon Cancer (Letter to Editor). (Eng) Cruse, J. P. (Surgical Unit, Univ. Coll. Hosp. Medical Sch., London WC1E 6JJ, England); Lewin, M. R.; Clark, C. G. *Lancet* 2(8094): 843-844; 1978.

Several errors in a previous report of a study of the protective effects of dietary fiber against chemically induced rat colon cancer are pointed out. In similar experiments of the authors, dietary fiber did not affect time to tumor or survival of dimethylhydrazine-treated rats significantly. Furthermore, the incidence of colon carcinoma was 100% at 1 yr in all dietary groups, regardless of fiber content. (4 refs)

78-6181 Mutagenic Properties of Ethylidene Gyromitrin and Its Metabolites in Microsomal Activation Tests and in the Host-Mediated Assay. (Eng) von Wright, A. (Food Res. Lab., Technical Res. Center Finland, Biologinkuja 1, SF-02150 Espoo 15, Finland); Niskanen, A.; Pyysalo, H. *Mutat Res* 54(2): 167-173; 1978.

The mutagenicity of the main poisonous hydrazine derivative of the edible mushroom false morel (ethylidene gyromitrin: EG) and its metabolites (N-methyl-N-formylhydrazine and N-methylhydrazine: MFH and MH, respectively) was tested by the microsomal and host-mediated assay. In the microsomal activation tests, the microsomal fraction of mouse liver did not increase the mutagenic or bacteriocidal properties of the EG and its metabolites to *Salmonella typhimurium* strain TA100. None of the compounds caused deaths due to poisoning when given by stomach tube to NMRI mice, although

two mice showed typical neurological symptoms after treatment with EG. EG and MH, but not MFH, inhibited growth of bacteria injected ip into the experimental mice. There were no increases in mutation frequency in the bacteria grown in treated mice compared with control bacteria. The data confirm the mutagenicity of MH and suggest that a bacteriocidal metabolite is formed from EG. (15 refs)

78-6182 Relationships Between the Mutagenic and Carcinogenic Effects of Hydrazine Derivatives. (Jpn) Shimizu, H. (Dept. Public Health, Jikei Univ. School of Medicine, Tokyo, Japan); Hayashi, K.; Takemura, N. *J. Hyg* 33(3): 474-485; 1978.

The mutagenic and carcinogenic effects of hydrazine derivatives were investigated. The microbial mutagenicity of 26 hydrazine compounds was tested with *Salmonella typhimurium* TA98, TA100, TA1537, in the presence or absence of S-9 mix. Eighteen of the 26 compounds were known carcinogens but the carcinogenicity of the remaining compounds was unknown. Five carcinogens such as 2-hydroxyethylhydrazine, butylhydrazine oxalate, phenylhydrazine HCl, beta-phenylthylhydrazine sulfate, and p-tolylhydrazine HCl, were mutagenic to TA100, with and without the S-9 mix. Two carcinogens, hydrazine hydrate and hydrazine sulfate, were mutagenic to TA100 only in the presence of the S-9 mix. 2,4-Dinitrophenylhydrazine and p,p'-oxybisbenzidine were mutagenic to TA100, with and without the S-9 mix. Phenylhydrazine HCl, p-tolylhydrazine HCl, and 2,4-dinitrophenylhydrazine were mutagenic to TA1537, with and without the S-9 mix. Phenylhydrazine HCl and p-tolylhydrazine HCl were mutagenic to TA98 with the S-9 mix, but 2,4-dinitrophenylhydrazine was mutagenic to TA98 without the S-9 mix. (78 refs)

78-6183 Transplacental Effect of Urethane on DNA Synthesis in Organ Cultures of Murine Embryonic Lung Tissues. (Rus) Kolesnichenko, T. S. (Dept. Carcinogenic Agents, Oncological Res. Center, Acad. Medical Sciences USSR, Moscow, USSR); Gusina, N. B. *Biull Eksp Biol Med* 86(10): 426-428; 1978.

The effect of transplacental exposure to urethane on DNA synthesis in embryonal lung tissue cultures was studied in line A mice. The pregnant mice embryonal lung tissue culture was studied in line A mice. The pregnant mice received single sc injection of 1 mg/kg urethane on day 15, 17, or 19 of embryogenesis. The embryos were extracted 1 day after injection, cultured, and examined 1, 7, 15, and 21 days later. DNA synthesis was determined from the ³H-thymidine labeling index. Embryonal lung tissue cultures from untreated pregnant mice served as controls. Urethane inhibited DNA synthesis during the first 24 hr; the labeling index was one-third of that found in the controls. After a normalization

the labeling index peaked on day 7 of culture; ie, 8 days after transplacental exposure to urethane. The labeling index decreased by day 15 of culture, but it was still higher than that of controls. On day 21 of culture, DNA synthesis was seen in the experimental explants only, but not in controls. (11 refs)

78-6184 Effect of Butylated Hydroxytoluene and Paraquat on Urethan Tumorigenesis in Mouse Lung. (Eng) Bojan, F. (Inst. Hygiene and Epidemiology, Univ. Medical Sch., 4012 Debrecen, Hungary); Nagy, A.; Herman, J. *Bull Environ Contam Toxicol* 20(4): 573-576; 1978.

The effect of administration of butylated hydroxytoluene (BHT) or Paraquat on urethan carcinogenesis was studied in the mouse lung. Female CFLP mice (30-35 days old) were treated with BHT (100-800 mg/kg ip) and injected with urethan (1 mg/g ip) 2 or 26 days before, 2-14 days after, or concomitantly with BHT. Other mice received a urethan injection (1 mg/g ip) concomitantly with or 1-4 days after Paraquat (5, 10, or 20 mg/kg ip). When given alone, BHT and Paraquat stimulated mitotic activity in type II alveolar cells and enhanced the carcinogenicity of urethan in the mouse lung. The potentiating effect of BHT was significant when the urethan was given 6-7 days after BHT; the yield of induced lung tumors increased in proportion to the BHT dose. Paraquat also significantly enhanced the number of lung tumors induced by urethan given 2 days after Paraquat; this effect was also dose-dependent. Previous reports have shown that lung tumors induced by urethan develop from type II alveolar cells. These results suggest that BHT and Paraquat enhance the carcinogenicity of urethan by increasing the number of proliferating target cells in the lung. (13 refs)

78-6185 Vinyl Carbamate as a Promutagen and a More Carcinogenic Analog of Ethyl Carbamate. (Eng) Ahl, G. A. (McArdle Lab. Cancer Res., Univ. Wisconsin Center Health Sciences, Madison, WI, 53706); Miller, J. A.; Miller, E. C. *Cancer Res* 38(11, part 1): 3793-3804; 1978.

This study was undertaken to test the hypothesis that vinyl carbamate (VC) is a proximate carcinogenic metabolite of ethyl carbamate (EC). When administered topically or ip at the same doses, VC was 10-50 times more active than EC in the initiation of skin tumors and lung adenomas in CD-1 and A/Jax mice. VC was mutagenic to *Salmonella typhimurium* A1535 and TA100, but only in the presence of ADPH-fortified rat or mouse liver mitochondrial supernatant fractions. This mutagenicity was strongly inhibited by cytochrome P-450 inhibitors. EC was not mutagenic for *S. typhimurium* in the presence or absence of liver fractions. Tests to detect VC as an in vivo metabolite of EC in 5-day-old CD-1 and adult A/Jax mice, performed under a variety of conditions, were unsuccessful. However, desaturation of the ethyl group during metabolism is suggested by the lower $^3\text{H}/$

^{14}C ratios in the hepatic DNA, ribosomal RNA, and protein of adult A/Jax mice administered [ethyl-1,2- ^3H ; 1- ^{14}C]-EC vs the $^3\text{H}/^{14}\text{C}$ ratios of the EC. The qualitatively similar, but much higher, carcinogenic activity of VC compared to that of EC suggests that the metabolic pathways of these two carbamates may converge in the formation of similar or identical electrophilic reactants that bind covalently to macromolecules in vivo and initiate carcinogenesis. (40 refs)

78-6186 Tolerances and Exemptions from Tolerances for Pesticide Chemicals in or on Raw Agricultural Commodities. (Eng) Johnson, E. L. (Office of Pesticide Programs, EPA, 401 M St. SW, Washington, DC, 20460). *Fed Regist* 43(219): 52486-52487; 1978.

An 0.2 ppm tolerance for residues of the herbicide isopropyl *m*-chlorocarbamate (CIPC) on soybeans has been established. The toxicological data supporting the proposed tolerance included a rat po LD study with an LD of 5-7.5 g/kg, a 2-yr rat feeding study with a no-observable-effect level (NOEL) of 2,000 ppm, a 1-yr dog feeding study with NOEL of 2,000 ppm, two 18-mo mouse carcinogenicity studies at a feeding level of 160 mg/kg/day (negative), a 116-wk mouse carcinogenicity study at a feeding level of 1,000 ppm (negative), a 33-mo hamster carcinogenicity study at a feeding level of 2,000 ppm, and a three-generation rat reproduction study (negative at 1,000 ppm). Desirable data that are lacking are a teratology study, a delayed neurotoxicity study, and an adequate study for effects on cholinesterase. The proposed 0.2 ppm tolerance of soybeans will not contribute residues to the human diet. The 2,000 ppm NOEL in the 2-yr rat feeding study supports an intake of 20 ppm in the human diet using a 100-fold safety factor. A 50 ppm tolerance was previously established for CIPC residues on potatoes, and interim 50 ppm tolerances were established residues on the hay of alfalfa, clover, and grass. (no refs)

78-6187 Chromosome Investigations of Persons Exposed to Dimethylcarbamoyl Chloride and Diethylcarbamoyl Chloride. (Eng) Fleig, I. (Occupational Medicine and Health Protection, BASF Aktiengesellschaft, 6700 Ludwigshafen/Rhein, W. Germany); Thiess, A. M. *J Occup Med* 20(11): 745-746; 1978.

Chromosome analyses were made of 10 chemical plant employees who had been exposed to dimethylcarbamoyl chloride (DMCC) and diethylcarbamoyl chloride (DECC) for 4-17 yr and 10 age-matched controls. The frequency of aberrant metaphases in the exposed group was 1.9%, while that in the controls was 1.3%. Chromosome-type aberrations comprised 1.1% of the aberrant metaphases in the exposed subjects and 0.8% in the controls. The differences were not statistically significant, indicating that DMCC and DECC exposure does not cause chromosome damage. (3 refs)

- 78-6188 Acetaldehyde Induces Cross-Links in DNA and Causes Sister-Chromatid Exchanges in Human Cells.** (Eng) Ristow, H. (Institut für Genetik, Freie Universität Berlin, Arnimalle 5-7, D-1000 Berlin 33, W. Germany); Obe, G. *Mutat Res* 58(1): 115-119; 1978.

Evidence is presented that acetaldehyde (AA), the first metabolite of ethanol, induces cross-links between calf thymus complementary DNA strands and induces sister chromatid exchanges (SCE's) in human lymphocytes. The DNA was incubated for 30 min at 37 C with 1 M AA and dialyzed overnight at 4 C. The DNA was then heated to 90 C, rapidly cooled, and reheated. The thermal transition midpoint (T_m) of AA-treated DNA was 66.2 C during the first heating and 66.6 C during the second. The T_m of control, untreated DNA was 70 C during the first heating, and no characteristic thermal transition was noted during the second. Thus, after heating and cooling, the hyperchromicity of AA-treated DNA was 60% of the original. In contrast, there was only an approx 20% loss of hyperchromicity with control DNA. It is suggested that cross-links were induced between the DNA strands by AA, leading to spontaneous reannealing of part of the DNA after the first heating and resulting in a partial reversal of the hyperchromic effect. Control DNA showed less spontaneous renaturing, possibly because of a lack of cross-links. Hyperchromicity after thermal denaturation was lowered as a function of AA treatment time; spontaneous reannealing after cooling was also related to treatment time. Both processes were dependent on AA concentration. Addition of 0.0005%-0.002% AA 24 or 48 hr before fixation of human lymphocyte cultures induced SCE's in a dose-dependent manner. The number of SCE's produced by the 24-hr treatment was almost doubled when cells were treated for 48 hr. These results indicate that ethanol, via AA, may be mutagenic in humans. (22 refs)

- 78-6189 Effect of Colostomy on Intestinal Carcinogenesis of Methylazoxymethanol Acetate in Rats.** (Jpn) Matsubara, N. (First Dept. Surgery, Sch. Medicine, Gifu Univ., Tsukasa-cho, Gifu 500, Japan). *Gifu Daigaku Igakubu Kiyo* 25(6): 501-520; 1977.

The effect of colostomy (COS) on the intestinal carcinogenicity of methylazoxymethanol acetate (MAM acetate) was studied in 5-wk-old Sprague-Dawley rats. Groups 1-3 rats underwent double COS, single COS, and no surgery, respectively, plus treatment with MAM acetate (25 mg/kg/wk x 10, iv). Group 4 rats served as untreated controls. Rats in Groups 1-3 developed multiple intestinal tumors, and the tumor incidence in these groups was similar. Tumor multiplicity was higher in Group 3 than in Group 2. The incidence of colon tumors in Group 1 was 64.5% in the oral one-third of the colon, 83.8% at the COS site, and 41.9% in the anal two-thirds; the mean number of tumors per rat in these locations was 1.4, 1.5, and 0.6, respectively. In Group 2 rats the tumor incidence was 28% in the oral section, 84.0% at the COS site, and 80.0% in the anal section; the mean number

of tumors per rat was 0.2, 1.4, and 1.0, respectively. MAM tumors in the anal section were at the oral stump of the colon and they were larger than those in other areas. In Group 1 tumor incidence was 72.2% in the oral section and 100% in the anal section, and the mean number of tumors per rat was 1.3 and 4.5, respectively. It was concluded that the carcinogenic metabolite of MAM acetate can reach the intestinal mucosa via the vascular system as well as through the biliary tract. (24 refs)

- 78-6190 Separation and Analysis of Various Carcinogenic Aromatic Amines and Their Metabolites.** (Eng) Weisburger, E. K. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD, 20014); Grantham, H.; Benjamin, T. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY) Vol. 2(Part 1), 2404 pp.; 1961-1972; 1978.

The continued application of various chromatographic techniques, including paper, thin-layer, gas, and high-pressure liquid chromatography, has led to improvements in the separation and identification of metabolites of three carcinogenic aromatic amines, N-2-fluorenylacetamide, 6-aminochrysene, and 2,4-toluenediamine. This in turn has increased knowledge of their metabolic pathways. (24 refs)

- 78-6191 The Distribution of DNA Repair Synthesis in Chromatin and its Rearrangement Following DNA Damage with N-Acetoxy-2-acetylaminofluorene.** (Eng) Tlsty, T. D. (Dept. Pathology, Washington Univ. Sch. Medicine, St. Louis, MO, 63110); Lieberman, M. W. *Nucleic Acids Res* 5(9): 3261-3273; 1978.

The distribution of DNA repair synthesis in the chromatin of confluent human diploid fibroblasts damaged with N-acetoxy-2-acetylaminofluorene (NA-AAF, 5-100 μ M) was studied. The amount of repair synthesis was dependent on NA-AAF concentration up to 10 μ M and much less at concentrations > 25 μ M. Kinetic analysis of staphylococcal nuclease digestion data showed that more repair synthesis occurred in nuclease-sensitive regions of chromatin than in nuclease-resistant regions. Data obtained by gel electrophoresis were in good agreement with the kinetic data, and they indicated that more repair synthesis occurred in linker DNA than in core DNA. Continuous-labeling and pulse-chase experiments showed that with time, an increasing proportion of nucleotides inserted during repair synthesis was present in the nuclease-resistant regions of chromatin. Rearrangement involved movement of label incorporated by repair synthesis into core DNA. Repair synthesis was a biphasic process. The data suggest that there is a relationship between rates of

synthesis and chromatin rearrangement. (28 refs)

6192 **An Investigation into the Effects of the Carcinogens Benzidine and 2-Acetylaminofluorine (AF) on the Control of Cholesterol Metabolism in the Rat and the Mouse.** (Eng) Depass, L. R. (Univ. Arkansas Medical Cent., Little Rock, AR, 72201). *Diss Abstr Int B* 39(5): 6192; 1978. (no refs)

6193 **Enhancement of Rat Hepatocellular-altered Foci by the Liver Tumor Promoter Phenobarbital: Evidence that Foci Are Precursors of Neoplasms and that Phenobarbital Acts on Carcinogen-induced Lesions.** (Eng) Tanabe, K. (Kagoshima Univ. Sch. Medicine, 1208-1, Shimo-Ogino, Kagoshima 890, Japan); Williams, G. M. *J Natl Cancer Inst* 61(5): 1311-1314; 1978.

The mechanism of liver tumor promotion by phenobarbital (PB) was investigated in inbred F344 rats fed 2-fluorenylacetylamide (FAA) and an iron-loading diet. Rats fed a diet containing 0.02% FAA, 0.8% 8-hydroxyquinoline, and 2.19% ferrous gluconate (FG) for 13 wk developed numerous iron-resistant, altered foci in every sub-lobule of the liver. Following cessation of carcinogen feeding, most foci reverted to iron accumulation and could no longer be detected by 24 wk, although some persisted for this interval. At the end of 24 wk after FAA termination, 33% and 78% of two groups of rats had tumors. When 0.05% PB was added to the diet for 24 wk after termination of FAA, the iron-resistant foci persisted, and the incidence of liver lesions was 78%-89%. The same levels of PB in the iron-loading diet of rats not given FAA previously did not induce iron-resistant foci. It was concluded that PB did not induce iron-resistant foci, but acted to retard the reversion of FAA-induced foci. (33 refs)

6194 **Diffusion Chamber Cultures for Mutagenic and Carcinogenic Assays (Meeting Abstract).** (Eng) Wang, C. C. (Dept. Experimental Biology, Roswell Park Memorial Inst., Buffalo, NY, 14263); Furukawa, M. *Mutat Res* 53(2): 201-202; 1978. (no refs)

6195 **Cyclophosphamide-induced Oncogenic Transformation, Chromosomal Breakage, and Sister Chromatid Exchange Following Microsomal Activation.** (Eng) Benedict, W. F. (Div. Hematology-Oncology, Dept. Medicine, Childrens Hosp. Los Angeles, Los Angeles, CA, 90027); Banerjee, A.; Venkatesan, N. *Cancer Res* 38(9): 2229-2234; 1978.

Cyclophosphamide (CP), an extensively used cancer chemo-

therapeutic agent, requires metabolic activation through a mixed-function oxygenase system. The capacity of this agent to produce oncogenic transformation and chromosomal damage, including increases in sister chromatid exchanges, was investigated in cultures of C3H/10T1/2CL8 mouse cells and A(T) Cl-3 Syrian hamster pseudodiploid cells with or without an exogenous liver metabolic activation system. This system was prepared from the livers of Sprague-Dawley rats inoculated with Aroclor 1254 (500 mg/kg). No oncogenic transformation or chromosomal aberrations were produced by CP in the absence of metabolic activation, whereas significant transformation, chromosomal breaks, and increases in sister chromatid exchanges were observed when the activation system was incorporated into the assays. The oncogenic transformation and chromosomal changes were completely eliminated by removing glucose 6-phosphate and NADP from the system. These studies emphasize the need for incorporating an activation procedure into short-term assays used to evaluate the mutagenic and/or oncogenic potential of various chemicals. (14 refs)

78-6196 **Acute Myelocytic Leukemia 11 Years Following Successful Therapy of Hodgkin's Disease. Report on the Problems of a Second Tumor.** (Ger) Ritter, J. (Kinderklinik der Stadt Braunschweig, Holwedestrasse 16, D-3300 Braunschweig, W. Germany); Oehme, J. *Med Klin* 73(39): 1360-1362; 1978.

Therapy-resistant acute myelogenous leukemia (AML) was diagnosed in a 21-yr-old man who underwent therapy for Hodgkin's disease at the age of 10 and for recurrences at ages 11 and 14-16 yr. The first therapy comprised surgical removal of the tumor, radiation (2,000 rads' focal dose), and several cycles of cytostatics (total doses: 23.6 g cyclophosphamide, 80 mg triethylenemelamine, 40 g procarbazine, 2.3 g chlorambucil, 130 mg vinblastine). Cyclic chemotherapy was repeated with the addition of Ultralan for the recurrences and discontinued 5 yr before the diagnosis of AML. For the first recurrence, radiation (1,600 rads' focal dose) was given. After the diagnosis of AML based on a bone-marrow biopsy, vigorous chemotherapy was given but the patient did not respond. An autopsy showed all the usual signs of AML with no microscopically evident infiltration of Hodgkin's disease. This case suggests that chemotherapy for Hodgkin's disease Stage I or II should not be used without consideration of the possibility of causing a second malignancy. This does not apply to the more advanced stages. A 5% incidence of AML in patients surviving 10 yr after radiotherapy + chemotherapy for Hodgkin's disease has been reported. (13 refs)

78-6197 **Acute Leukemia Following Cyclophosphamide Therapy for Sjogren's Syndrome.** (Eng) Hochberg, M. C. (Rheumatology Div., Good Samaritan Hosp., 5601 Loch Raven Blvd., Baltimore, MD, 21239); Shulman, L. E. *Johns Hopkins Med J* 142(6): 211-214; 1978.

A 56-yr-old woman with Sjogren's syndrome (SS) developed acute myelomonocytic leukemia after 31 mo of cyclophosphamide (CP) therapy (50 mg/day initially, with the dose eventually increased to 150 mg/day). Since the leukemia occurred 12 yr after the onset of SS, CP may have been a significant etiologic factor. (22 refs)

78-6198 Isolation and Structure Determination of Mutagenic Substances in L-Glutamic Acid Pyrolysate. (Eng) Yamamoto, T. (Shizuoka Coll. Pharmacy, 2-2-1 Oshika, Shizuoka-shi, Shizuoka 422, Japan); Tsuji, K.; Kosuge, T.; Okamoto, T.; Shudo, K.; Takeda, K.; Iitaka, Y.; Yamaguchi, K.; Seino, Y.; Yahagi, T.; Nagao, M.; Sugimura, T. *Proc Jpn Acad Ser B Phys Biol Sci* 54(5): 248-250; 1978.

Two strongly mutagenic substances produced by pyrolysis of L-glutamic acid were isolated and their structures determined. Pyrolysis was performed by heating 10 kg L-glutamic acid, collecting the resulting tar, distilling the basic fraction, and then purifying this fraction by silica gel, Sephadex column, alumina column, and thin-layer chromatography. Acidification of the two resulting bands with 0.5% HBr produced two hydrobromides with differing Rf values. These compounds were designated Glu-P-1 and Glu-P-20 mutagenicity, determined by the Ames assay, increased with each purification step. The activity of the final purified compounds was 13,700 and 1,600 revertants/ μ g. Mass spectroscopy and elemental analysis determined that the formulas of Glu-P-1 and Glu-P-2 were $C_{11}H_{10}N_4$ and $C_{10}H_8N_4$, respectively. Nuclear magnetic resonance and UV spectra indicated that the two compounds differed by an aromatic methyl group. The structure of Glu-P-1 was determined to be 2-amino-6-methyldipyrido[1,2-a:3',2'-d]imidazole, that of Glu-P-2 2-aminodipyrido[1,2-a:3',2'-d]imidazole. (7 refs)

78-6199 Azaserine Carcinogenesis: Organ Susceptibility Change in Rats Fed a Diet Devoid of Choline. (Eng) Shinozuka, H. (Dept. Pathology, Univ. Pittsburgh, Sch. Medicine, Pittsburgh, PA, 15261); Katyal, S. L.; Lombardi, B. *Int J Cancer* 22(1): 36-39; 1978.

The effects of feeding a choline-deficient (CD) diet on the carcinogenicity of azaserine (AS) in the rat pancreas were investigated in groups of male Wistar rats. Groups I and II were fed a CD or choline-supplemented diet, respectively, and inoculated ip with AS (30 mg/kg in 2 ml saline) 2x/wk for the first 4 wk and 1x/wk thereafter, for a total of 14 injections. Control groups were fed either of the diets and inoculated with saline. Four to seven animals from each group were killed 1, 4, and 6 mo after the first injection, and the liver and pancreas were examined histologically. None of the controls developed hepatic or pancreatic tumors, and no hepatomas were observed in the 12 Group II rats. In contrast, 3/5 and 5/7 Group I rats killed at 4 and 6 mo, respectively, had multiple hepatomas. Both Groups I and II rats

developed multiple atypical acinar cell nodules (AACN) in the pancreas after 4 mo. However, the number of AACN was significantly smaller in Group I rats (mean, 7.6) than in Group II (mean, 16.0). It is concluded that the CD diet changed the organ susceptibility to the carcinogenic action of AS, enhancing hepatocarcinogenesis and reducing the effect of the carcinogen on the pancreas. (16 refs)

78-6200 Persistence of DNA Damage in Rat Pancreas Following Administration of Three Carcinogens and/or Mutagens. (Eng) Lilja, H. S. (Dept. Pathology, University of New Hampshire Medical Sch., Hanover, NH, 03755); Curphey, J. D.; Yager, J. D.; Longnecker, D. S. *Chem Biol Interact* 22(2): 287-295; 1978.

Alkaline sucrose gradients were used to detect and follow the persistence of DNA damage in the pancreas and liver of Fischer 344 and Wistar/Lewis rats after they were given single or multiple weekly injections of azaserine (AZ: 10 mg/kg), MNCO (N-methyl-N-nitrosocarbonyl-L-ornithine) (MNCO: 10 or 218 mg/kg/wk) or neutral red (96 or 288 mg/kg/wk). Results were compared with the carcinogenicity and mutagenicity of each compound. Damaged DNA was present in pancreas 1 hr after AZ administration, and damage persisted in both pancreas and liver for > 1 wk. Damage to pancreatic and hepatic DNA was more extensive 1 wk following 6 wk or 6 mo of weekly AZ injections than at 1 wk after a single injection. Damage to pancreatic DNA was detectable in rats 1 hr after either dose of MNCO. Pancreatic DNA damage was not apparent 1 wk after 72 mg/kg MNCO, but it was detectable 1 wk after 218 mg/kg. Significant pancreatic DNA damage was detected 1 wk after 6 wk or 6 mo of weekly injections of 72 mg/kg. Damage to hepatic DNA was detectable at either 72 or 218 mg/kg whether administered once or weekly in the above protocols. DNA damage was present in pancreas and liver 1 hr after injection of 96 mg/kg neutral red but not at 1 wk. Limited DNA damage was detectable in liver but not in pancreas 1 wk after a dose of 288 mg/kg. Persistent DNA damage was also detectable in liver but not in pancreas after six weekly injections of 96 mg/kg. The results indicate that the relative persistence of DNA damage may be an accurate indication of the organotropic carcinogenic potential of AZ, MNCO and neutral red administered at nontoxic dose levels. 78-6201 On Mutagens in Foods, Especially on Compounds from Pyrolysis of Protein (Meeting Abstract). (Eng) Nagao, M. (Natl. Cancer Center Res. Inst., Tokyo, Japan); Yahagi, T.; Kawachi, T.; Seino, Y.; Honda, M.; Matsukura, N.; Sugimura, T.; Wakabayashi, K.; Tsutsui, K.; Kosuge, T. *Mutat Res* 53(2): 239; 1978. (no refs)

78-6202 Characteristic Features of Tryptophan Metabolite-induced Hemoblastoses in Various Animals.

ciency. (Rus) Khrustalev, S. A. (Cancer Res. Center, Moscow, USSR). *Probl Gematol Pereliv Krovi* 23(9): 33-36; 1978.

The leukemogenic activity of 3-indolylacrylic acid (3-IAA) and 2-aminoacetophenone (2-AAP) was studied in Syrian hamsters, guinea pigs, and rats. Animals received sc injections of small doses of these tryptophan metabolites for 2-3 months. 3-IAA induced hemoblastoses in 10/60 hamsters, 4/71 guinea pigs, and 1/30 rats; 2-AAP induced hemoblastoses in 5/5 hamsters, 3/70 rats, and 0/20 guinea pigs (incidence of spontaneous hemoblastoses in hamsters, rats, and guinea pigs was 3/33, 2/60 and 1/40 respectively). (4 refs)

6203 **Significance of the Reaction of Nitrite with Tryptophan.** (Eng) Nakai, H. (Natl. Inst. Animal Industry, Chiba-Shi, 280, Japan); Cassens, R. G.; Greaser, M. L.; Woolford, G. *J Food Sci* 43(6): 1857-1860; 1978.

The reaction of sodium nitrite with tryptophan was studied spectrophotometrically to determine the significance of the reaction in cured meats. Although the tryptophan content of meat is relatively low, it is an essential amino acid and the indole nitrogen presents a secondary amine for reaction. Absorption at 330 nm indicated the formation of nitrosotryptophan. The reaction proceeded rapidly at pH 4.0, slowly at pH 5.0 and very sluggishly at pH 5.5 or higher. Experiments with dipeptides and acetyltryptophan indicated that nitrosation of the indole nitrogen was promoted if the primary amino group of tryptophan was blocked. It is concluded that, in view of the concentration of reactants and pH in cured meat, the environment for the nitrosation of tryptophan is favorable. (18 refs)

6204 **Mutagenic Properties of Nitrosated Spermidine.** (Eng) Kokatnur, M. G. (Dept. Pathology, Louisiana State Univ. Medical Center, New Orleans, LA, 70112); Murray, M. L.; Correa, P. *Proc Soc Exp Biol Med* 131(1): 85-88; 1978.

The nitrosation of spermidine resulted in direct-acting mutagens in the Ames assay using *Salmonella typhimurium* 1535. The mutagenic effect was catalyzed by thiocyanate and inhibited by ascorbic acid. The extent of formation of mutagenic compounds was dependent upon the pH of the medium, with an optimum at 4.0 and a range of 3.0-6.0. These results suggest that the nitrosated spermidine model fulfills many of the requirements of the hypothesis that gastric cancer and its precursor lesions may be induced by the intragastric formation of mutagenic/carcinogenic N-nitroso compounds. It yields a direct-acting mutagen; it has an optimum pH range very similar to that found in the gastric juice of human populations at high risk for gastric cancer, as a result of chronic atrophic gastritis; its mutagenicity may be enhanced by thiocyanate ions, which are present in human gastric juice, and spermidine is found in foods prominent in the diet of populations at high gastric cancer risk. (18 refs)

78-6205 **Effect of L-Ethionine on Macromolecular Synthesis in Mitogen-Stimulated Lymphocytes.**

(Eng) Zabos, P. (Dept. Pediatrics and Biochemistry, Mount Sinai Sch. Medicine City Univ. New York, New York, NY); Kyner, D. A.; Seide-Kehoe, R.; Acs, G.; Christman, J. K. *Biochim Biophys Acta* 520(1): 139-152; 1978.

The effects of L-ethionine (Eth) on macromolecular synthesis and modification in mitogen-stimulated human and mouse lymphocytes was studied. DNA synthesis in phytohemagglutinin- or concanavalin A-stimulated lymphocytes was completely inhibited by 2-4 mM Eth. Eth also inhibited the methylation of transfer RNA and prevented the mitogen-induced increase in the activity of histone-modifying enzymes, but it had little or no effect on commitment to DNA synthesis, rates of RNA and protein synthesis, size of the ATP and guanosine triphosphate pools, or the occurrence of morphological changes characteristic of blast formation. Thus, Eth permitted a quiescent lymphocyte to enter the G₁ stage of the cell cycle and to progress toward S, although it blocked DNA synthesis. These effects of Eth were completely reversible: removal of Eth after ≥ 24 hr of exposure resulted in the rate of RNA methylation, and an increase in the activity of histone-modifying enzymes. The results suggest that Eth may inhibit DNA synthesis by inhibiting a methylation reaction critical to initiation of that synthesis. (37 refs)

78-6206 **Some Improvements in the Mutagenicity Testing of Chemicals with *Bacillus subtilis*, *Salmonella typhimurium* and *Escherichia coli*; Results with 500 Chemicals (Meeting Abstract).** (Eng) Hirano, K. (Natl. Inst. Genetics, Misima, Sizuoka-ken, Japan); Narui, K.; Sadaie, Y.; Kada, T. *Mutat Res* 53(2): 200; 1978. (no refs)

78-6207 **Biochemical Studies on Rats with Insulin-secreting Islet Cell tumors Induced by Streptozotocin: With Special Reference to Physiological Response to Oral Glucose Load in the Course of and after Tumor Induction.** (Eng) Kazumi, T. (Second Dept. Internal Medicine, Kobe Univ. Sch. Medicine, Kobe, Japan); Yoshino, G.; Yoshida, Y.; Doi, K.; Yoshida, M.; Kaneko, S.; Baba, S. *Endocrinology* 103(5): 1541-1545; 1978.

Pancreatic islet cell tumors were induced in 32/49 male Wistar rats surviving 9 mo or longer after treatment with streptozotocin (S: 65 mg/kg iv) alone (Group 1), nicotinamide (500 mg/kg ip) + S (Group 2), or picolinamide (250 mg/kg ip) + S (Group 3). Of a total of 73 tumors, there were 14 in Group 1 rats, 47 in Group 2 rats, and 12 in Group 3 rats. In glucose (G) tolerance tests, elevation of blood G following intragastric G was depressed throughout the study in Group 2 rats, and it was significantly depressed at 7 mo. Conversely, mean plasma insulin (I) levels, which had remained unchanged up to 7 mo after treatment, rose abruptly 30 min

after G loading (44 to 167 μ U/ml) at 9 mo treatment. In tumor-bearing rats, G levels after loading were always significantly lower than those of tumor-free rats, but mean plasma I levels rose significantly from 47 to 132 μ U/ml within 30 min of G administration. Tumor-bearing rats tended to develop hypoglycemia when appearing moribund 13-26 mo after treatment. The mean I concentration in 11 islet cell tumors was 401 U/g wet wt, as opposed to the control mean of 14.0 U/g wet wt. These findings suggest that pancreatic islet cell tumors induced by streptozotocin alone or by combined treatment are insulin-secreting. (8 refs)

78-6208 Tumorigenic Action of Streptozotocin on the Pancreas and Kidney in Male Wistar Rats. (Eng) Kazumi, T. (Second Dept. Internal Medicine, Kobe Univ. Sch. Medicine, Kusunoki-cho 7-chome, Ikuta-ku, Kobe 650, Japan); Yoshino, G.; Fujii, S.; Baba, S. *Cancer Res* 38(7): 2144-2147; 1978.

The carcinogenic action of streptozotocin (STZ) was investigated in male Wistar rats. Pancreatic islet cell tumors were induced in 38 of 44 rats which survived 9-14 mo following various treatment schedules with STZ. Single iv injections of STZ alone at doses of 30, 40, 50, and 65 mg/kg produced adenomas of pancreatic islet cells in 8 of 9 (89%), 6 of 7 (86%), 2 of 4 (50%), and 1 of 2 (50%) rats, respectively. The neoplasms were seen in all of 8 rats given a single ip injection of picolinamide (250 mg/kg) 15 min before a single iv injection of STZ (65 mg/kg). Pancreatic islet cell tumors developed in 13 of 14 (95%) rats given a single ip injection of nicotinamide (500 mg/kg) 15 min before a single iv injection of STZ (65 mg/kg). Renal tumors were seen in only 3 rats treated with STZ and nicotinamide. None of the rats used in this study developed hepatic tumors. The results demonstrate that STZ, even in a dose of 30 mg/kg, has an exceedingly marked tumorigenic action on the rat pancreas, while it has little effect on the kidney and no effect on the liver. (19 refs)

78-6209 Oncogenic Effects of Antimitotic Chemotherapy. Observation of Four Cases. (Fre) Carcassonne, Y. (Clinique des maladies du sang, Hopital de la Conception, 136, rue Saint-Pierre, F 13385 Marseille Cedex 4, France); Blanc, A. P.; Gastaut, J. A.; Sebahoun, G. *Ann Med Interne (Paris)* 129(3): 181-186; 1978.

Four men developed cancer after undergoing treatment with chemotherapeutic agents. Three patients, ages 24, 53, and 64 yr, had a blood profile and symptoms indicative of acute myeloblastic leukemia after the use of chlorambucil, azathioprine, or 6-mercaptopurine for glomerulonephritis in two cases and immunosuppression prior to kidney transplant in one case. These three patients died of infection or hemorrhage. The fourth patient, age 52 yr, developed a lymphoma after 3 yr of treatment with chlorambucil for glomerulone-

phritis (total dose, 5,598 g). Combination chemotherapy and radiation have succeeded in controlling the malignancy. Possible mechanisms of action of the drugs are discussed. (no refs)

78-6210 Gastric Cancer in Rats after Chronic Intraperitoneal Application of Sap of Green Potatoes (*Solanum tuberosum* L.). (Eng) Ivankovic, M. (Inst. Toxicology and Chemotherapy, German Cancer Research Center, Im Neuenheimer Feld 280, D-69 Heidelberg, W. Germany). *Experientia* 34(5): 645; 1978.

Sap from the green tops of potatoes (*Solanum tuberosum* L.) was injected ip (0.25 ml) once weekly into 12 BD IX rats to determine its carcinogenicity. Two rats developed adenocarcinomas of the glandular stomach, and two developed papilloma and a squamous cell carcinoma of the forestomach. Control rats developed tumors. Chemical analysis (unpublished) revealed the presence of several volatile N-nitrosamines in the sap. (no refs)

78-6211 Acute Myelogenous Leukemia Following Chlorambucil Treatment. Report of Two Cases. (F) Fiere, D. (Service d'Hematologie, Hopital Edouard Herriot, 5 place d'Arsonval, F 69374 Lyon Cedex 2, France); Fellenz, P.; Vu Van, H.; Coiffier, B. *Nouv Presse Med* 7(9): 756; 1978.

Two 55-yr-old patients treated with chlorambucil for 2 and 4 yr for nephrotic syndrome and rheumatoid polyarthritis respectively, developed acute myelogenous leukemia after treatment periods of 3 and 3.5 yr. (1 ref)

78-6212 Inhibition of Deoxyribonucleic Acid Synthesis by Diisopropanolnitrosamine, N-Methylnitrosourea, Azaserine and 4-Hydroxyaminoquinoline 1-oxide after Partial Pancreatectomy in Rats. (Eng) Konishi, K. (Dept. Oncological Pathology, Cancer Center, Nara Medical Univ., Kashiwara, 634, Nara, Japan); Denda, A.; Kawabuchi, H.; Takahashi, S.; Sunagawa, M.; Kondo, H. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404-2405; 1978.

The effect of a single injection of dimethylnitrosamine (DMH: 100 mg/kg ip), ethionine (700 mg/kg ip), streptozotocin (65 mg/kg iv), diisopropanolnitrosamine (DIPN: 1,000 mg/kg ip), N-methylnitrosourea (MNUT: 1,000 mg/kg ip), azaserine (5 mg/kg ip), and 4-hydroxyaminoquinoline 1-oxide (4-HAQO: 7 mg/kg iv) on DNA

thesis of pancreatic acinar cells after partial pancreatectomy (64%) was studied in male Wistar rats. The carcinogens administered 3 days after the operation, when DNA synthesis was at its max level, and the animals were sacrificed later. DNA synthesis was not inhibited by DMN or aflatoxine, both nonpancreatic carcinogens. It was inhibited by DIPN (57.9%), MNUT (76.4%), azaserine (71.7%), and AAO (82.1%), all pancreatic nonendocrine carcinogens. The effect of streptozotocin, a pancreatic endocrine carcinogen on DNA synthesis was not clear. Dose-dependent inhibition of DNA synthesis was seen with azaserine and 4-HAQO but not with NMUT or DIPN. The inhibition of DNA synthesis by 4-HAQO lasted for at least 24 hr; it recovered to control values by 72 hr. Mechanisms involved in the inhibition of pancreatic DNA synthesis by these carcinogens require further study. (36 refs)

78-6213 Enzymatic Removal of O⁶-Methylguanine from DNA by Mammalian Cell Extracts. (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033). *Biochem Biophys Res Commun* 84(1): 166-173; 1978.

Extracts from various rat tissues were incubated with methylated DNA or chromatin, and their abilities to catalyze the removal of labeled O⁶-methylguanine (OMG) from acid-precipitable DNA were compared. The four substrates were dimethylnitrosamine (DMN)-treated DNA and chromatin, isolated from the livers of rats inoculated with 50 mg/kg ³H-DMN (3.5 Ci/millimole) 20 min before death, and methyl-N-nitrosourea (NMU)-treated calf thymus DNA and NMU-treated rat liver chromatin, obtained by incubating the two substrates with 0.05 mM ³H-NMU (1.055 Ci/millimole) in vitro. In the first experiment, the substrates were incubated for 60 min at 37 C in the presence or absence of liver protein. The rat liver extracts were able to catalyze the loss of OMG from acid-precipitable DNA when incubated with all four substrates. The most convenient substrate was NMU-treated calf thymus DNA, because it was the easiest to prepare and the extracts showed max activity on this substrate. Prolonged incubation of the substrate with high concentrations of liver protein led to a loss of up to 50% OMG. In the second experiment, using extracts from different rat tissues and NMU-treated calf thymus DNA, liver extracts had the greatest activity. Kidney extracts had about 35% of the liver activity, and extracts from lung, colon, small intestine, and brain were much less active. The enzyme responsible did not appear to be an N-glycosidase, because labeled OMG could be detected in the supernatant, even though >50% of this base was lost from the DNA. The released radioactivity was methanol, which is consistent with the possibility that the reaction involves a demethylase action on the DNA substrate or on an oligonucleotide derived from it. 78-6214 Further Assessment of a Test for Determining the Mutagenicity of Compounds Metabolised In

Vivo in the Rat (Meeting Abstract). (Eng) Newton, M. F. (Dept. Biology as Applied to Medicine, Middlesex Hosp. Medical Sch., Cleveland St., London W1P 6DB, England); Lilly, L. J. *Mutat Res* 53(2): 241; 1978. (1 ref)

78-6215 Carcinogen Induced Alterations in DNAase I Release of N³-Methyladenine from Liver Chromatin. (Eng) Rao, P. M. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario M5S 1A8, Canada); Rajalakshmi, S.; Sarma, D. S. *Chem Biol Interact* 22(2/3): 347-351; 1978.

To determine whether carcinogens alter gene organization, Fischer rat liver chromatin DNA was labeled in vivo with ¹⁴C-dimethylnitrosamine to generate methylated bases such as N⁷-methylguanine, O⁶-methylguanine, and N³-methyladenine. The isolated chromatin was treated with pancreatic deoxyribonuclease I (DNase I) to digest 50% of the chromatin DNA, and the distribution of the methylated purines in the DNase I-digestible and nondigestible fractions was determined. Resistance to DNase I was attributed in part to the association of proteins with these regions of DNA. Accordingly, any alteration in the distribution of these dimethylnitrosamine-induced methylated bases in the chromatin fractions as a result of the subsequent administration of carcinogen (N-methyl-N-nitrosourea) was used as a parameter to indicate a change in DNA-protein association in the chromatin brought about by the carcinogen. The observed release of carcinogen-modified bases in the DNase I-digestible fractions of chromatin may represent an interaction of the carcinogen with regions of chromatin that are probably transcribable. The results also indicate that carcinogens can alter the DNA-protein association (gene organization) in such a way that DNA regions in chromatin accessible to nuclease digestion before carcinogen administration are rendered inaccessible subsequent to its administration. 78-6216 De Novo and Repair Replication of DNA in Liver of Carcinogen-treated Animals. (Eng) Craddock, V. M. (Toxicology Unit, Medical Res. Council Lab., Woodmansterne Road, Carshalton, Surrey, SM5 4EF, England); Henderson, A. R. *Cancer Res* 38(7): 2135-2143; 1978.

The effect of various carcinogens on de novo and repair replication of DNA in the liver of Wistar rats was investigated. Single ip injections of diethylnitrosamine (100, 200, or 250 mg/kg), ethyl methanesulfonate (300 or 500 mg/kg), aflatoxin (0.5 or 2.0 mg/kg), and retrorsine (160 mg/kg) induced DNA repair replication in vivo but did not alter de novo synthesis 2 hr after injection. Single ip injections of carbon tetrachloride (4,000 mg/kg) and ethionine (500 mg/kg) also induced repair replication but only after a delay period of 17 hr, suggesting that the repair was that of damage caused by an indirect mechanism, such as by deoxyribonuclease activity resulting from lysosomal damage (carbon tetrachloride) or

from nonenzymic reaction of DNA with a metabolite of the carcinogen that is slow to accumulate in the liver (S-adenosylmethionine after ethionine). A single ip injection of thioacetamide (150 mg/kg) did not cause detectable repair replication, a result that correlates with the lack of evidence for a reaction between thioacetamide and DNA. 78-6218 Some Peculiarities in the Kinetics and Mechanism of Transformation of Paramagnetic Heme and Non-heme Iron Complexes in Carcinogenesis. (Eng) Saprin, A. N. (Dept. Kinetics Chemical and Biological Processes, Inst. Chemical Physics, Acad. Sciences USSR, Moscow, USSR). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1207-1218; 1978.

The kinetics of changes in cytochrome P-450 (CCP-450) levels in the Wistar rat liver during dimethylaminoazobenzene (DAB)- and diethylnitrosamine (DEN)-induced carcinogenesis was studied by electron spin resonance. During the precancerous stage, CCP-450 levels in the hyperplastic tissue increased to 2.5 times that of controls and then dropped at the time of tumor appearance and subsequent tumor growth. During the terminal stages of tumor growth, CCP-450 levels decreased fourfold compared with control levels. The free-radical concentration in microsomes increased more than four times during the precancerous stage, compared with normal liver. This increase was observed prior to the decrease in CCP-450 levels, which suggests that the free radicals may be responsible for the decrease. Liver tissue from rats fed both DAB and butylated hydroxytoluene (BHT), a nontoxic inhibitor of free-radical processes, showed no significant change in free-radical concentrations from those in normal tissue, and no tumors developed after 1 yr. However, DAB + BHT increased CCP-450 levels at times earlier than the increase in free-radical concentration. This seems to indicate that the anticarcinogenic properties of BHT are due to its induction of high levels of CCP-450 in rat liver, which promotes the detoxification of DAB, rather than to its inhibition of free-radical formation. 78-6219 Hematologic Disorder after MOPP Treatment of Hodgkin's Disease. (Eng) Moloney, W. C. (Massachusetts General Hosp., Boston, MA); Long, J. C.; Ferrucci, J. T.; Groopman, J. E.; Aisenberg, A. C.;

Galbadini, J. J.; Dermirjian, Z. N.; Hirsch, M. S.; Man, R. M.; Stossel, T. P. *N Engl J Med* 299(17): 946; 1978.

The case report of a man with Hodgkin's disease (HD: cellularity type) who, 6 yr later at age 35, developed a myelogenous or erythromyelocytic leukemia with terminal pneumocystis or fungal pneumonia is described. In addition, the patient had viral hepatitis, repeated episodes of bacterial pneumonia, osteomyelitis, cytomegalovirus infection, and hypersensitivity syndrome. After the diagnosis of HD, 4 courses of MOPP [nitrogen mustard, vincristine (Oncovin), procarbazine, and prednisone] were administered over 18 mo. The patient improved and was well and active during the next 4 yr. Throughout the final illness there was no evidence of recurrent HD. The repeated bacterial and viral infections indicated a lack of immunologic defenses. Skin tests for purified protein derivative of tuberculin, streptokinase-streptolysin, and monilia were negative. Whether the splenectomy after the first diagnosis and the MOPP therapy contributed to the lowering of host defenses is a matter of speculation. The leukemia may be related to an immunologic defect caused by the therapy or to one of many other factors, such as injury to lymphoid tissue by the immunosuppressants, or perhaps with activation of a leukemogenic virus. (10 refs)

78-6220 Dominant Lethal Effects of Triethylenemelamine in the Guppy *Poecilia reticulata*. (Eng) Mathews, J. G. (Sch. Biology, Georgia Inst. Technology, Atlanta, GA, 30332); Favor, J. B.; Crenshaw, J. W. *Mutat Res* 54(2): 149-157; 1978.

Triethylenemelamine [2,4,6-tris(aziridinyl)-s-triazine, TEM] was selected to test the potential of an experimental dye for detecting dominant lethal events in the common guppy, *Poecilia reticulata*. Dominant lethal effects were induced by ip injection of males with 0, 0.1, 0.2, or 0.4 mg/kg TEM dissolved in Fish Ringer's soln or by immersion of males in the same solns used for the injections for 24 hr. All treated males were subsequently mated to virgin females 1 day after treatment, and the females were removed 24 hr later. 7 days following the establishment of matings, the females were sacrificed and dissected, and live and dead embryos were counted. The percentage of dead embryos increased and the total number of embryos decreased with TEM dose. The injection method had a more deleterious effect than the immersion method, but the reason(s) for this finding are not clear. The results are compared with those of *Drosophila* and mammalian studies. (17 refs)

78-6221 DNA Alkylation and Neuro-Oncogenesis by 3,3-Dimethyl-1-phenyltriazene. (Eng) Coccaro, H. K. (Max-Planck-Institut für Hirnforschung, D-5000 L, 91, W. Germany); Hauenstein, E.; Kolar, G. F.; Kleihues, P. *Acta Neuropathol (Berl)* 43(1-2): 105-109; 1978.

The role of DNA alkylation in the initiation of malignant transformation by 3,3-dimethyl-1-phenyltriazene (DMPT) was studied using BD-IX rats. Following a single sc injection

¹⁴C-DMPT (100 mg/kg) into pregnant females on gestation day 21, the concentrations of 7-methylguanine and O⁶-methylguanine in the brains and livers of the fetuses were similar. Within 2 days after birth, however, the liver DNA values were significantly higher than in the brain values, and this trend continued during postnatal growth. In all organs investigated, the concentrations of 7-methylguanine in the DNA of adult mice 12 hr after the last of five weekly injections of ¹⁴C-DMPT (50 mg/kg each) were higher than those observed 12 hr after a single injection (50 mg/kg). This effect was most pronounced in the ileum, brain, and lung. The O⁶-methylguanine concentrations following multiple doses of ¹⁴C-DMPT were increased only in brain and lung DNA relative to the concentrations observed after a single dose. The data suggest that the efficient excision repair capacity of the CNS is a significant factor in the organ-specific carcinogenicity of DMPT and related carcinogens. (24 refs)

78-6222 **Expression of TEM-induced Damage to Postmeiotic Stages of Spermatogenesis of the Mouse during Early Embryogenesis. II. Cytological Investigations.** (Eng) Burki, K. (Swiss Inst. Experimental Cancer Res., CH-1066 Epalinges, Switzerland); Sheridan, W. *Mutat Res* (1): 107-115; 1978.

Analyses were made of triethylenemelamine (TEM)-induced chromosome damage to postmeiotic male germ cells during early mouse embryogenesis. Male DBA/2J mice treated with 2 or 0.4 mg/kg TEM were mated with CD-1/CR females. For the analysis of first-cleavage metaphases, pregnant females were treated with 2.5 mg/kg colchicine on day 1 of pregnancy, and the eggs flushed from their oviducts approximately 1 hr later. In addition, embryos were flushed from the oviducts (day 2), junction (day 3), or uteri (day 4) of pregnant females without colchicine pretreatment. The frequencies of first-cleavage metaphases exhibiting structural aberrations (all of the chromosome type) and the frequencies of two-cell embryos and of four- to eight-cell embryos containing nuclei accompanied by micronuclei or nuclei connected by bridges were closely correlated to frequencies of preimplantation loss of embryos recorded in a dominant lethal test. The frequencies of morulae/blastulae containing blastomeres with micronuclei showed a close correlation to the frequencies of total (pre- and postimplantation) loss of embryos. This indicates that the expression of TEM-induced chromosomal damage is delayed and, thus, the damage could persist undetected in very early stages of embryogenesis. (12 refs)

78-6223 **Mutagenicity of Arylalkyl- and Arylacetyl-triazenes in Respect to Their Reaction Mechanisms (Meeting Abstract).** (Eng) Pool, B. L. (Inst. Experimental Toxicology and Chemotherapy, German Cancer Res. Center, Heidelberg, W. Germany). *Mutat Res* 53(2): 249; 1978. (no refs)

78-6224 **Carcinogenicity of Triethanolamine in Mice and Its Mutagenicity after Reaction with Sodium Nitrite in Bacteria.** (Eng) Hoshino, H. (Radiobiology Div., Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Tanooka, H. *Cancer Res* 38(11, part 1): 3918-3921; 1978.

The carcinogenicity of triethanolamine (TEA) was examined in male and female ICR-JCL mice fed a diet containing 0.3% or 0.03% (wt/wt) TEA from the age of 6 wk to death or sacrifice. The incidence of various tumors was significantly higher in TEA-fed mice than in controls. Female mice showed a high incidence of lymphoid tissue tumors (22%), but these tumors were absent in males. Other types of malignant tumors found were independent of sex. Mice fed the TEA-containing diet survived as long as the controls; the survival rate was 50% at 85 wk in females and at 65 wk in males. TEA was not mutagenic to *Bacillus subtilis*, with or without liver microsomes. When TEA was incubated with sodium nitrite under acidic conditions or when the mixture was heated, a direct-acting mutagen was produced, but its mutagenic activity was destroyed by rat liver microsomes. N-Nitrosodiethanolamine (NDEA) was detected in the reaction mixture by thin-layer chromatography, but it may not be the main mutagenic product, because this product was a stable and direct mutagen and its mutagenic activity was destroyed by liver enzymes, whereas NDEA is unstable and does not induce mutation in *B. subtilis* by itself. The chemical nature of the mutagenic product in the TEA:sodium nitrite mixture has not been identified. (11 refs)

78-6225 **Analytical Investigations of Hexamethylenetetramine Samples for the Presence of Volatile Organic Compounds and of In Vitro Nitrosation Metabolites (Nitrosamines).** (Ger) Roper, H. (Institut für Organische Chemie und Biochemie, Universität Hamburg, Martin-Luther-King-Platz 6, D-2000 Hamburg 13, W. Germany); Heyns, K. *Z Lebensm Unters Forsch* 167(3): 145-149; 1978.

Analysis of four hexamethylenetetramine (HMT) samples by gas chromatography/mass spectrometry revealed the presence of formaldehyde, methylamine, chloroform, and trimethylamine N-oxide, but no secondary or tertiary aliphatic amines. No dimethylnitrosamine was formed in in vitro nitrosation reactions with HMT + sodium nitrate in acidic solution. In view of these findings, it is proposed that HMT be reconsidered for use as a food additive. (36 refs)

- 78-6228 **Direct Study of Alkylating Agent-RNA Interaction by ^{13}C Nuclear Magnetic Resonance Spectroscopy.** (Eng) Chang, C. (Dept. Medicinal Chemistry and Pharmacognosy, Sch. Pharmacy and Pharmacal Sciences, Purdue Univ., W. Lafayette, IN, 47907); Lee, C. G. *Cancer Res* 38(11, part 1): 3734-3736; 1978.

The interactions of four methylating agents and *Torula* yeast RNA were studied by ^{13}C nuclear magnetic resonance (NMR) spectroscopy, a direct method that eliminates all processes that may cause decomposition and structural alteration. In addition, spectral interference is reduced, product distribution can be determined at an early alkylation stage, and the amount of alkylating agent can be reduced. Methylation reactions were carried out at room temperature and pH 7 by treating an 8.5-ml aqueous soln of 500 mg lyophilized RNA with 1.5 millimoles of methyl methanesulfonate (MMS: 130 μl), dimethyl sulfate (DMS: 142 μl), or 1-methyl-1-nitrosourea (MNNG: 221 mg) for 12 hr or with 1-methyl-3-nitro-1-nitrosoguanidine (MNNG: 221 mg) for 259 hr. Each reaction mixture was then dialyzed and lyophilized repeatedly, and NMR samples were prepared. Based on integration curves, the agents could be classified into two groups according to biological potency: (1) weakly mutagenic/carcinogenic, MMS and DMS; (2) strongly mutagenic/carcinogenic, MNU and MNNG. In conclusion, from the chemical shift analyses and the spectral integration curves, the reactive sites, the product distributions and specificity of the different methylating agents, and the degree of N-7 methylation of guanosine could be determined. The results show the potential application of ^{13}C NMR spectroscopy in establishing the mechanisms of chemical carcinogenesis and mutagenesis. (32 refs)

- 78-6229 **N-Methyl-N-nitrosourea Mediated Conversion of O⁶-Methylguanine to Xanthine.** (Eng) Rao, P. M. (Dept. Pathology, Univ. Toronto, Medical Sciences Building, Toronto, Ontario M5S 1A8, Canada); Rajalakshmi, S.; Serma, D. S.; Krepinsky, J. *Chem Biol Interact* 22(2/3): 341-346; 1978.

The in vitro alkylation by N-methyl-N-nitrosourea (MNU) of rat liver chromatin DNA prelabeled in vivo with ^{14}C -dimethylnitrosamine (^{14}C -DMN) was studied. The standard reac-

tion condition was to incubate 4.24 micromoles (μmol) of (^{14}C) methylguanine [O^6 -(^{14}C)meG] in 0.1 N HCl at 70 C 45 min or at 37 C for 16 hr. In all cases, demethylation of O^6 -meG yielded guanine. However, when treated with MNU (29.1 μmol) and 0.1 N HCl, O^6 -meG was converted mostly to xanthine. Observations that guanine is not deaminated by MNU and 0.1 N HCl as effectively as O^6 -meG and that guanine is detected in the formation of xanthine from meG suggest that the deamination of O^6 -meG precedes the demethylation step in its conversion to xanthine. It is suggested that if the conversion of O^6 -meG to xanthine occurs in vivo at the macromolecular level, the mutagenicity of N-nitroso-N-alkylamides can be due to not only the formation of a miscoding lesion of O^6 -meG, but also to its conversion to xanthine. (9 refs)

- 78-6230 **C-Type Virus Particles in Cell Cultures of Chemically Induced Glioma in Sprague-Dawley Rats.** (Rus) Anzil, A. P. (Electron Microscopy Lab., Max Planck Inst. Psychiatry, Munich, W. Germany); Stavrou, A.; Blinzinger, K. *Vopr Onkol* 24(9): 30-32; 1978.

Long-term cultures were prepared from mixed anaplastic gliomas induced by N-methyl-N-nitrosourea (6 mg/kg/wk for at least 10-12 mo) in Sprague-Dawley rats. Electron microscopy revealed budding and large numbers of cytoplasmic and extracellular C-type virus particles in many cultures. This is the first report of a chemically induced glioma associated with C-type virus particles in rats. The characteristics of this rat glioma are being studied. (10 refs)

- 78-6231 **Surface Structure of Fetal Rat Brain Cells During Neoplastic Transformation in Cell Culture.** (Eng) Haugen, A. (Dept. Pathology, Gade Inst., Univ. Bergen, N-5016 Haukeland Hosp., Bergen, Norway); Laerum, O. D. *J Natl Cancer Inst* 61(6): 1415-1422; 1978.

The surface microstructure of fetal BD IX rat brain cells undergoing neoplastic transformation in long-term cell culture after they were exposed to a single transplacental pulse of N-ethyl-N-nitrosourea (ENU; 75 $\mu\text{g/g}$) on gestation day 18 was investigated by scanning electron microscopy. The fetal brain cells (FBC) were transferred into monolayer culture 24 hr after exposure and maintained in culture for up to 1.5 yr. After 3 wk, ENU-pretreated FBC showed focal proliferation of neural cells on an underlayer of flat, epithelioid cells. The neural cells exhibited varying forms of numerous dorsal ruffles and an increased number of other surface microprojections. Between the 40th and 100th day, nodules of bipolar and multipolar neural cells with a complex surface microstructure, including many blebs and ruffles and an increased number of microvilli, were observed. After 100 days, more rapidly proliferating, morphologically altered cells

ned piled-up foci, which resulted in a homogeneous population of cells with numerous long microvilli, large ruffles, blebs over the whole surface. Attempts to establish permanent cell lines were successful in 4/13 trials. Three of these lines were tumorigenic upon retransplantation into baby at around 273 days. The surface structure of cells from solid tumors was the same as that seen in vitro, exhibiting numerous microvilli and ruffling membranes over the whole surface. Thus, surface alterations characteristic of neoplastic cells were observable >100 days before the cells became tumorigenic. (29 refs)

6232 **Mutagenicity of Several Classes of Antitumor Agents to *Salmonella typhimurium* TA98, TA100, and TA92.** (Eng) Seino, Y. (Biochemistry Div., Natl. Cancer Center Res. Inst., Tsukiji, Chuo-ku, Tokyo 104, Japan); Nagao, M.; Yahagi, T.; Hoshi, A.; Kawachi, T.; Shimura, T. *Cancer Res* 38(7): 2148-2156; 1978.

The mutagenic activities of various antitumor agents which included 19 antimetabolites, 5 antibiotics, 5 alkylating agents, 1 alkaloid, 1 enzyme, and 1 adrenal steroid hormone were tested on *Salmonella typhimurium* strains TA100, TA98, and TA92. Four of the anticancer agents, busulfan, carbazilquinone, 1-(4-amino-2-methylpyrimidine-5-yl)methyl-3-(2-chloroethyl)-3-nitrosourea hydrochloride, and pipobroman were found to be mutagenic for the first time. The known mutagenicities of five others, daunomycin hydrochloride, mitomycin C, 6-mercaptopurine, and cyclophosphamide were confirmed. Since there is a demonstrated correlation between mutagenicity in this bacterial test system and the carcinogenic potential in laboratory animals, the development of new chemotherapeutic agents that have no mutagenicity in such bacterial test systems is desirable from the standpoint of possibly decreasing the risk of latent drug-induced cancer in patients undergoing chemotherapy. (33 refs)

6233 **Alloxan Induced Leukemoid Condition in a Fresh Water Teleost *Clarias batrachus*** (Letter to Editor). (Eng) Agrawal, P. (Dept. Zoology, M.M./P.G. College, Modinagar 201 204, District Ghaziabad, Uttar Pradesh, India); Goel, K. A. *Curr Sci (Bangalore)* 47(15): 555-560; 1978.

The possible leukemogenic action of alloxan was demonstrated in 42 fish (*Clarias batrachus*) inoculated im with 50 mg/kg of the compound every 3 days. The number of WBC increased after 10-40 days, and after 40 days, 50% of the total WBC were immature. Mitosis was also observed in some WBC at this time. (2 refs)

6234 **Mutagenicity of Nitro Compounds in *Drosophila melanogaster*** (Meeting Abstract). (Eng)

78-6235 **Flagyl and Radiation-induced Chromosome Breakage (Letter to Editor).** (Eng) Prosser, J. S. (Natl. Radiological Protection Board, Harwell, Didcot, Oxon OOX11 0RQ, England); White, C. M. *Br J Radiol* 51(608): 654-655; 1978.

Preliminary observations of the effect of Flagyl (metronidazole) on the yield of x-ray-induced dicentric aberrations in human lymphocytes from anoxic and normal venous blood are presented. Flagyl increased the dicentric yield from irradiated anoxic blood significantly, but the dicentric levels were not as high as those observed in normal venous blood. The dicentric yield from blood at venous oxygen tension was not changed. (7 refs)

78-6236 **The Mutagenic Screening of Fourteen Imidazo Compounds Using a Modified Ames' Test.** (Eng) Turner, J. V. (Dept. Tissue Pathology, Inst. Medical and Veterinary Science, P.O. Box 14, Rundle St., Adelaide, S. Australia, 5000, Australia); Ward, A. D.; Freeman, C. G. *Mutat Res* 57(2): 135-139; 1978.

Eight imidazo[1,2-a]pyrimidine derivatives and six cyclic guanidine derivatives were synthesized and tested for mutagenic activity by a modified Ames *Salmonella typhimurium* assay using strains TA100, TA98, and TA1537, with or without microsomal activation. No mutagenicity or inhibition of growth was observed with any test compound. (6 refs)

78-6237 **High Pressure Liquid Chromatographic Assay for α Hydroxylation of N-Nitrosopyrrolidine by Isolated Rat Liver Microsomes.** (Eng) Chen, C. B. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY, 10595); McCoy, G. D.; Hecht, S. S.; Hoffmann, D.; Wynder, E. L. *Cancer Res* 38(11, part 1): 3812-3816; 1978.

A high-pressure liquid chromatographic assay for the α hydroxylation of N-nitrosopyrrolidine (NPY) by isolated hepatic microsomes from Aroclor-induced or noninduced male F-344 rats is described. This sensitive assay may allow determination of the role of hydroxylation in NPY carcinogenesis. Mixtures consisting of NPY, rat liver microsomes, and an NADPH-generating system were incubated at 37 C. The major α hydroxylation product, 2-hydroxytetrahydrofuran, was trapped by the addition of 2,4-dinitrophenylhydrazine to form 4-hydroxybutyraldehyde-2,4-dinitrophenylhydrazone, which was then quantitated by reverse-phase high-pressure liquid chromatography. Under optimal conditions, the α hy-

droxylation of NPY was linear for at least 90 min and had characteristics typical of the microsomal mixed-function oxidase system, such as inhibition by carbon monoxide and induction by pretreatment of the rats with Aroclor (500 mg/kg). Aroclor induction resulted in a greater than twofold increase in the α hydroxylation rate compared with noninduction. There was a close correspondence between the binding affinity and the α hydroxylation of NPY by the microsomes. This is the first available method for in vitro studies of the α hydroxylation of a cyclic nitrosamine. (28 refs)

78-6238 The Effect of the Microsomal Enzyme Inhibitor, Piperonyl Butoxide, on Mutagenesis in *Drosophila melanogaster* (Meeting Abstract). (Eng) Lindsay, R. J. (Sch. Biological Sciences, Flinders Univ. South Australia, Bedford Park, S.A. 5042 Australia); Clark, A. M. *Mutat Res* 53(2): 221; 1978. (no refs)

78-6239 Structural Requirements for Mutagenic Activities of N-Heterocyclic Bases in the Salmonella Test System. (Eng) Matsumoto, T. (Central Res. Inst., Japan Tobacco and Salt Public Corp., 6-2, Umeokaoka, Midoriku, Yokohama, Kanagawa 227, Japan); Yoshida, D.; Mizusaki, S.; Tomita, H.; Koshimizu, K. *Agric Biol Chem* 42(4): 861-864; 1978.

The effects of structural changes on the mutagenic activities of quinoline (Q), isoquinoline (IQ), phenanthridine (PA), benzo(f)quinoline [B(f)Q], benzo(h)quinoline [B(h)Q], and their α -amino derivatives were studied in the *Salmonella typhimurium* test system. All mutagenic compounds tested required the liver microsomal fraction (S-9 mix) in order to express their mutagenic activity. PA, B(f)Q, and Q were mutagenic to strains TA98 and TA100, B(h)Q was mutagenic only to TA100, and IQ was nonmutagenic to both strains. The mutagenic activities of Q and the BQ's increased greatly after amination in the α -position of the pyridine moiety, but amino-IQ was nonmutagenic to TA98 and TA100. The addition of a benzene ring to 2-amino-Q markedly increased its mutagenic activity, whereas the addition of a benzene ring to the pyridine moiety of 2-amino-Q only slightly increased mutagenic activity. The mutagenic activity of 2-amino-B(f)Q, but not those of 2-amino-B(h)Q and 9-amino-PA, was markedly stimulated by B(f)Q, B(h)Q, and PA in the presence of S-9 mix. Norharman enhanced the effect of 2-amino-B(f)Q in the presence of S-9 mix. The results indicate that among the α -amino heterocyclic bases, a three-ring system is more mutagenic than a two-ring system and the fused position of the three-ring system affects mutagenic activity and strain specificity. (15 refs)

78-6240 Carcinogenicity of 4-Chloronitrosopiperidine in Sprague-Dawley Rats. (Eng) Lijinsky, W.

(Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Taylor, H. W. *Z Krebsforsch* 92(2): 217-220; 1978.

The carcinogenicity of 4-chloronitrosopiperidine was tested in 15 Sprague-Dawley rats who were given the compound in their drinking water (0.005% soln) for 27 wk (total dose, 1.5 mg). Seven animals died by 41 wk, all 15 by 58 wk. Two rats had tumors: 7 had liver tumors, 5 had esophageal tumors, 2 tumors of the nonglandular stomach, and 2 tumors of the nasal turbinates. Several rats had tumors of more than one organ. The mortality pattern of these rats was almost identical with that of rats treated with a considerably higher dose (440 mg) of nitrosopiperidine. It is concluded that the addition of a single chlorine atom to the nitrosopiperidine molecule changes the chemistry so that the compound is more active in producing liver neoplasms. (5 refs)

78-6241 Formation and Biological Effect of N-Nitrosopiperazine Compound from Piperazine Pesticide Triflorine. (Eng) Borzsonyi, M. (Dept. Morphology, Natl. Inst. Public Health, Budapest, Hungary); Pinter, A.; Torok, G.; Surjan, A.; Nadasdi, L. *IARC Sci Publ* (19): 477-484; 1978.

In vitro experiments were conducted to determine the formation of the carcinogen dinitrosopiperazine (DNPZ) from the fungicide Triflorine (TF: N,N'-piperazinidylbis-2,2,2-trichloroethylidenebisformamide), and in vivo experiments were conducted in Swiss/Leiden mice to determine tumor incidence and morphology after intragastric administration of TF (300 mg/kg 2 x/wk). One hundred of the mice all received 0.05% sodium nitrite in their drinking water (Group 1), and 50 were treated with TF alone (Group 2). Tumor incidence was highest in Group 1 (104 tumors), and most of the tumors were lymphomas. The proliferating tumor cells corresponded to lymphoblasts. Ten Group 1 mice had stomach tumors, four gastric papillomas and six invasive squamous cell carcinomas. Prior to day 180, however, there were no morphological alterations in the glandular mucosa of the stomach. Most of the intestinal tumors that developed were in the duodenum and jejunum, and tumors appeared to develop from surface foci of atypical epithelial cells. Tumor incidence was similar in Group 2 animals, animals treated with sodium nitrite only, and untreated controls, and it was much less than that of Group 1 (25 tumors/401 mice). The results indicate that various tumors can be induced by DNPZ formed in vivo from TF. In the in vitro nitrosation of TF, 100 g of TF was dissolved in 270 ml 6 N HCl and 47.6 g of sodium nitrite dissolved in 270 ml distilled water was added slowly. After 24 hr at 4 C, 15.8 g of 1,4-dinitropiperazine was formed. (8 refs)

78-6242 Chemical Carcinogen Alteration of SV40 Virus Induced Transformation of Normal Human Cell Populations In Vitro. (Eng) Milo, G. E. (Dept. Physiologic

Chemistry, Coll. Medicine, Ohio State Univ., 1900 Coffey Road, Columbus, OH, 43210); Blakeslee, J. R.; Hart, R.; and others. *Chem Biol Interact* 22(2/3): 185-197; 1978.

The in vitro interactions of chemical carcinogens with a transforming DNA virus in human cells were determined to an index of the cocarcinogenicity of these agents. The frequency of simian papovavirus 40 (SV40)-induced transformation of human foreskin fibroblasts or neonatal foreskin cells was enhanced after pretreatment of the cells with naphthylacetamide (NA-2), N-methyl-N'-nitrosoguanidine (MNNG), acetyl-2-fluorenylacetylamide (N-Ac-AAF), benzo(a)pyrene (BP), aflatoxin B₁ (AFB₁), propane sultone, β -propiolactone (β PL), 4-nitroquinoline oxide (4-NQO), methylmethanesulfonate (MMS), or diethylnitrosamine (DEN). Pretreatment with 4-NQO, MMS, MNNG, or DEN inhibited transformation, but posttreatment with AFB₁, β -PL, or NA-2 did not alter transformation, similar to the action of N-Ac-AAF and BP. All carcinogens that altered transformation after pretreatment damaged cellular DNA. Pretreatment with posttreatment with 3-methylcholanthrene (3-MC) or 1,2-dimethylbenz(a)anthracene (7,12-DMBA) did not damage cellular DNA and did not enhance transformation. Moreover, pre- or posttreatment with other weak or noncarcinogens that did not damage cellular DNA also did not alter transformation-induced transformation. All foci formed in the cocarcinogen-treated cultures, whether the carcinogen inhibited or enhanced transformation, were virus-directed. Although a similar pattern of response existed for carcinogens that either enhanced or inhibit transformation, each of the carcinogens that enhanced or inhibited foci formation damaged cellular DNA. Moreover, those carcinogens that enhanced focus formation, compared with the carcinogens that inhibited focus formation, exhibited similar DNA damage profiles. (35 refs)

78-6243 Breast Cancer at a Psychiatric Hospital Before and after the Introduction of Neuroleptic Agents. (Eng) Wagner, S. (Office Medical Director, Norristown State Hosp., Norristown, PA, 19401); Mantel, N. *Cancer Res* 38(9): 2703-2708; 1978.

The possible association between breast cancer and treatment with neuroleptic agents was investigated in 5,463 women who had or underwent breast biopsy at the Norristown State Hospital (in Pennsylvania) between 1940 and 1974. The method of proportionality was used to evaluate the breast cancer incidence. Cases of breast cancer were related to deaths from other cancers and to deaths from all causes other than breast cancer. Deaths and cancers that occurred within 1 yr of hospital admission were excluded from the analysis. To allow for a 10-yr transition period and for latency in the development of breast cancer, comparison was made between the 15 yr preceding the introduction of neuroleptic agents into medical practice (1940-1954) and the second decade after their introduction (1965-1974). Although neuroleptic agents were used extensively to treat the patients at the hospital, there was no statistically or medically significant change in the indicated

incidence of breast cancer at the hospital during the neuroleptic period. The study did not rule out the possibility that neuroleptic agents might have some effect on breast cancer after a very long latency period. (no refs)

78-6244 Investigation on the Tester Strain of *Saccharomyces cerevisiae* for Primary Screening of Environmental Mutagens (Meeting Abstract). (Eng) (Div. Genetics, Natl. Inst. Radiological Sciences, Chiba, Japan); Machida, I.; Saeki, T.; Yoshikawa, K. *Mutat Res* 53(2): 240; 1978. (no refs)

78-6245 Neoplastic Transformation of Human Diploid Cells In Vitro after Chemical Carcinogen Treatment. (Eng) Milo, G. E. (Dept. Physiological Chemistry and Veterinary Pathobiology, Ohio State Univ., 1900 Coffey Road, Columbus, OH, 43210); DiPaolo, J. A. *Nature* 275(5676): 130-132; 1978.

The in vitro neoplastic transformation of primary or low-passage cells from 10 human foreskin cell populations by the carcinogens propane sultone (PS: 5 μ g/ml), β -propiolactone (PL: 13 μ g/ml), aflatoxin B₁ (AFB₁: 10 μ g/ml), N-methyl-N'-nitro-N-nitrosoguanidine (MNNG: 0.1 μ g/ml), 4-nitroquinoline 1-oxide (4-NQO: 0.002 μ g/ml), and ethyl methane sulfonate (EMS: 10.0 μ g/ml) is reported. To obtain transformation, the normal cells were blocked in the G₁/S interphase, released, and then treated with carcinogen during the S phase. Removal of the carcinogen 12 hr later coincided with the end of the S phase. After treatment, the proliferation of the unaffected cell population was purposely inhibited. Posttreatment population doubling No. 20 was found to be suitable for determining the ability of the transformed cells to grow in 0.5% soft agar. Cells transformed by PS, PL, and AFB₁ had 100% colony-forming ability in soft agar, whereas only 25%-70% of those transformed by 4-NQO, EMS, and MNNG formed colonies. A close correlation between growth in soft agar and tumor formation in nude mice was obtained. Injection of cells into the subcapsular area of the mice produced sc tumors 18-25 days later. The tumors were composed of multiple vacuolated cell types having predominantly a syncytial network with an eosinophilic cytoplasm and ovoid basophilic nuclei. The tumors were classified as undifferentiated mesenchymal tumors. To date, tumors have been serially subpassaged three times. (15 refs)

78-6246 Rat Liver Microsome-Mediated Binding to DNA of 3-Amino-1-methyl-5H-pyrido[4,3-b]indole, a Potent Mutagen Isolated from Tryptophan Pyrolysate. (Eng) Hashimoto, Y. (Faculty Pharmaceutical Sciences, Univ. Tokyo, Bunkyo-ku, Tokyo, Japan); Takeda, K.; Shudo, K.; Okamoto, T.; Sugimura, T.; Kosuge, T. *Chem Biol Interact* 23(1): 137-140; 1978.

The binding of 3-amino-1-methyl-5H-pyrido(4,3-b)indole (Trp-P-2) to calf thymus DNA was measured after incubation with liver microsomes from male Wistar rats treated with polychlorinated biphenyl (500 mg/kg, ip). The radioactivity from ^3H -Trp-P-2 bound tightly to DNA in the presence of rat liver microsomes. The binding was not affected by reprecipitation, dialysis, or gel chromatography. The amount of Trp-P-2 bound to DNA was about 60 $\mu\text{mol/mol}$ P, which increased to 230 $\mu\text{moles/mole}$ P after three successive incubations of the DNA with Trp-P-2 and microsomes. Trp-P-2 bound significantly to poly G in the presence of microsomes, but it did not bind to poly A, poly C, or poly U in the presence or absence of microsomes. After acid hydrolysis, DNA with bound Trp-P-2 gave more than two fluorescent spots on thin layer chromatography. (8 refs)

78-6247 Guanyl O⁶-Arylation and O⁶-Arylation of DNA by the Carcinogen N-Hydroxy-1-naphthylamine. (Eng) Kadlubar, F. F. (Natl. Center Toxicological Res., Jefferson, AR, 72079); Miller, J. A.; Miller, E. C. *Cancer Res* 38(11, part 1): 3628-3638; 1978.

Two O⁶-substituted deoxyguanosine adducts formed by the reaction of N-hydroxy-1-naphthylamine (N-HO-1-NA), a carcinogen for liver, urinary bladder, and other tissues of humans and animals, with DNA at pH 5 were isolated and characterized. N-HO-1-NA reacted with nucleic acids and protein at pH 5 to form covalently bound derivatives with 3-20 naphthyl residues/1,000 monomer units. The level of binding was in the following order: DNA > polyguanylic acid > denatured DNA and ribosomal RNA > serum albumin > transfer RNA > polyadenylic acid. The carcinogen did not react with nucleosides and nucleotides. Binding of N-HO-1-NA to DNA was not inhibited by the addition of nucleosides, nucleotides, methionine, or glutathione. Enzymatic hydrolysis of the DNA-containing naphthyl residues yielded three nucleoside arylamine adducts, N-(deoxyguanosin-O⁶-yl)-1-naphthylamine, 2-(deoxyguanosin-O⁶-yl)-1-naphthylamine, and the decomposition product of the latter. Direct evidence for acid-dependent arylnitrenium ion formation was obtained by isotope exchange upon solvolysis of N-HO-1-NA in acidic H₂¹⁸O, and carbocation formation was indicated by formation of the solvolysis products 1-amino-2-naphthol and 1-amino-4-naphthol. The potential role of the guan-O⁶-yl naphthylamine adducts in the initiation of urinary bladder carcinogenesis through the formation of promutagenic lesions in DNA is discussed. (64 refs)

78-6248 Follicular and Parafollicular Adenomas in the Thyroids of Rats Treated with Thiamazole. (Fre) Stoll, R. (Laboratoire de la Fondation Bergonie, 180 rue de St. Genes, F 33076 Bordeaux Cedex, France); Faucouneau, N.; Maraud, R. *Ann Endocrinol (Paris)* 39(3): 179-189; 1978.

The development of follicular cell (FC) and parafollicular (PFC) adenomas in the thyroids of rats treated with the thyroid drug thiamazole (TMZ: 1-methyl-2-mercaptimidazole) was followed. Three groups of male Wistar rats, ages 3, 6, and 8 mo respectively, were administered 0.1% 0.2% TMZ in their drinking water for 1, 3, 8, 9, 12, or 17 mo. The rats were killed and their thyroids examined immediately after the end of treatment or at various times to 17 mo later. Control rats of same age were also sacrificed. Immediately after treatment, animals on TMZ for 1-3 mo had thyroid glands that were larger and heavier than controls. Hypertrophy and hyperplasia were evident, but no adenomas were observed. Rats sacrificed immediately after 8 mo treatment had one or more FC adenomas, some of which occupied an entire lobe of the thyroid. PFC adenomas developed in rats starting 6 mo after the cessation of TMZ treatment. In rats treated for 3 mo, the PFC adenomas were only type observed after cessation of treatment; in rats treated for 8 mo or more, PFC adenomas coexisted with FC adenomas. Among the 72 rats treated for 9-14 mo, 64 had adenomas, 46 FC, 7 PFC, and 11 FC + PFC types. The percentage of C cells (or parafollicular cells, of which the PFC adenomas are composed) increased with age of rat. C-cell hyperplasia occurred in rats during TMZ treatment, but no PFC adenomas were formed until treatment had stopped. It is concluded that both types of adenomas are related to the hypothyroid condition and its duration, but the hormonal mechanism involved differs. (19 refs)

78-6249 3-Hydroxyxanthine: Transplacental Effect on Ontogeny of Related Sulfate Metabolism in Rats and Mice. (Eng) Anderson, L. M. (Memorial Sloan-Kettering Cancer Center, Walker Lab., Rye, NY 10580); McDonald, J. J.; Budinger, J. M.; Mountain, I. B.; Brown, G. B. *J Natl Cancer Inst* 61(6): 1405-1410; 1978.

Sulfotransferase activity toward the carcinogenic parent N-oxide 3-hydroxyxanthine (3-OH-X) was detected in fetal Sprague-Dawley (SD) rats and (C57BL/6 x BALB/c)F₁ mice delivered near term at a rate of approx 25% of adult values. The activities of 3-OH-X sulfotransferase, 3'-phosphoadenosine-5'-phosphosulfate (PAPS) sulfotransferase and ^3S -p-nitrophenol (PNP) sulfotransferase were compared in an assay using homogenized fetal livers. At day 21 of gestation, 3-OH-X sulfotransferase activity in fetal livers was significantly lower than adult values, and treatment of pregnant females with 3-OH-X (25 mg/day 4x) did not alter the enzyme levels. After birth, the activity rose linearly to adult values at 6 wk. PNP sulfotransferase was low or absent in fetal livers, but after birth, it eventually reached adult levels at 6 wk. PAPS sulfotransferase was 2-3 times higher in fetal livers than in livers of pregnant females or 6-wk-old rats, and it fell steadily to adult values after birth. 3-OH-X was injected ip into pregnant rats four times at doses of 1, 5, 10, or 25 mg on days 19-21 of gestation; pregnant mice were injected ip with 50 mg/kg on days 17 and 18. Of 10 male rat offspring receiving 25 mg/kg doses prenatally, 3 had liver tumors (including 2 hepatoma

compared with 0/29 controls. Kidney disease at all doses was common in male rats, but no liver abnormalities were seen in female offspring. Prenatal administration of 3-OH-X in rats resulted in significantly increased prenatal deaths, but the survivors had fewer lung adenomas at 20 mo of age (6/28 vs 21/50 controls). The association of low levels of activating enzyme in the male fetal rat liver with the weak but significant tumorigenic effect of 3-OH-X supports the hypothesis that enzymatic activation may be a limiting factor in transplacental carcinogenesis. (25 refs)

78-6250 Increased Incidence of Mammary Tumors in Rats After Direct or Transplacental Exposure to 3-Hydroxyxanthine. (Eng) Anderson, L. M. (Memorial Sloan-Kettering Cancer Center, Walker Lab., Rye, NY, 10580); Teller, M. N.; Budinger, J. M.; Brown, G. B. *J Natl Cancer Inst* 61(6): 1411-1414; 1978.

Rats exposed directly or transplacentally to N-oxide 3-hydroxyxanthine (3-OH-X) developed mammary tumors at significantly increased rates over controls. Among female Wistar rats that received 3-OH-X sc 1x/wk in varying doses, beginning at age 9 days, 4 wk, or 10 wk, there was a significantly increased proportion of animals bearing mammary tumors and an increased number of tumors/rat in all dose groups except the highest (7 mg x 22). In that group, the rats died before mammary tumors could develop. Histologically, the tumors included fibroadenomas, adenomas, and carcinomas. Administration of 3-OH-X to males sc or to females did not increase mammary tumor incidence. Female offspring of Sprague-Dawley mothers given four ip injections of 25 mg 3-OH-X during pregnancy developed mammary tumors significantly more often than controls (93% vs. 57%). The number of tumors/rat was also significantly increased, but the number of females with at least one malignant mammary tumor (3/14) was similar to that in control group (1/16). Lower prenatal doses of 3-OH-X did not increase male mammary tumor incidence, but male tumor incidence was greater than the control incidence in all dose groups. Because the tumors initiated by transplacental exposure to 3-OH-X remained dormant for many months, prolactin may have stimulated their growth as the rats aged. (19 refs)

78-6251 Excretion and Distribution of Morpholine Salts in Rats. (Eng) Tanaka, A. (Dept. Medical Chemistry, Natl. Inst. Hygienic Sciences, 18-1, Kamiyoga 1-chome, Setagaya-ku, Tokyo, Japan); Tokieda, T.; Namikawa, S.; Osawa, M.; Yamahara, T. *J Food Hyg Soc Jpn* 19(3): 229-234; 1978.

The elimination, organ distribution, and metabolism of morpholine HCl (MPL HCl) and MPL palmitate were studied in male Wistar rats by chemical assays using gas-liquid chromatography and by radioassays using ¹⁴C-MPL. For the chemical assay, the MPL HCl doses were 500 mg/kg po and

250 mg/kg iv; for the radioassays, the doses were 200 mg/kg po and 150 mg/kg iv. ¹⁴C-MCL palmitate (400 mg/kg) was given po through a stomach tube. MPL HCl was eliminated very rapidly after po and iv administration. In the chemical assays, > 85% appeared in urine after 24 hr, and 90% was excreted over 3 days. Very small amounts were excreted in feces. Similar results were obtained for both salts by radioassay. Over 5 days, 80%-90% was excreted in urine and 3%-10% in feces, with fecal excretion of the palmitate being slightly higher than that of the HCl. Thin-layer chromatography confirmed that MPL was excreted unchanged. MPL accumulated primarily in muscle and intestine, and significant quantities remained in the intestine for 12 hr. Elimination from other organs was very rapid. Adipose tissue showed the lowest affinity for MPL, regardless of route of administration. From these findings, it would appear that MPL is an inert substance in the rat body. (15 refs)

78-6252 Chromosome Investigations on Workers Exposed to Styrene/Polystyrene. (Eng) Thiess, A. M. (Occupational Medicine and Health Protection, BASF Aktiengesellschaft, 6700 Ludwigshafen/Rhein, W. Germany); Fleig, I. *J Occup Med* 20(11): 747-749; 1978.

Cytogenetic studies were carried out in 12 chemical plant employees with 3-39 yr possible exposure to styrene, and urinary mandelic acid levels were studied in 58 additional employees. The frequency of aberrant metaphases in the chromosomes of the 12 workers studied was 1.9%; this frequency was the same as that in 12 controls. Forty-eight workers excreted < 30 mg/liter mandelic acid in the urine; 8 excreted 30-50 mg/liter, and only 2 excreted > 50 mg/liter. The concentrations of styrene at the plant were usually < 1 ppm; in areas where the concentrations were higher, but < 10 ppm, exposure lasted only 3-5 min at a time. (9 refs)

78-6253 Mutagenicity of Styrene and Styrene Oxide in Drosophila Tests (Meeting Abstract). (Eng) Sorsa, M. (Dept. Genetics, Univ. Helsinki, Helsinki, Finland); Laamanen, I.; Vainio, H. *Mutat Res* 53(2): 266-267; 1978. (no refs)

78-6254 Carcinogenicity and Mutagenicity of 5-Nitroacenaphthene and Tetrachlorobenzidine. (Eng) Takemura, N. (Dept. Public Health, Jikei Univ. Sch. Medicine, Tokyo, Japan); Hashida, C.; Shimizu, H. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1329-1336; 1978.

The carcinogenicity of 5-nitroacenaphthene (NAN) and tetrachlorobenzidine (TCB) was tested in male and female Wistar rats and Syrian golden hamsters and in female dd strain mice; their mutagenicity was tested on *Salmonella typhimurium* strains TA100 and TA98. Twelve of 30 female rats given NAN (1% of diet for 4 mo) lived > 200 days after the start of feeding and developed malignant tumors: 1 rhabdomyosarcoma, 2 sebaceous squamous cell carcinomas in the ear duct, 5 intraductal breast carcinomas, and 10 adenocarcinomas of the small intestine. Ten of 20 female rats given NAN (1% of diet for life) lived > 200 days and developed tumors in the ear duct (4), breast (3), kidney (1), and liver (1). Thirteen of 24 female hamsters given NAN (1% of diet for 6 mo) survived > 270 days, and 7/13 developed cholangiomas. None of the males developed tumors. Seventeen of the 20 mice given TCB (0.1% of diet for life) survived > 300 days and developed 14 malignant lymphomas, 2 mammary carcinomas, and 1 mammary fibrosarcoma. Both chemicals were mutagenic on *S. typhimurium* TA100 and TA98 with metabolic activation. Precautions should be taken when these chemicals are handled occupationally. (4 refs)

78-6255 Cytological Effects of the Antihelminthic Agent Oxytocanide on Mitotic Chromosomes of *Allium cepa* L. (Eng) Reddy, P. V. (Dept. Zoology, Kakatiya Univ., Vidyanayapuri Warangal 506 009, India); Murthy, D. K.; Subramanyam, S. *Indian J Exp Biol* 15(1): 1073-1074; 1977.

The effect of the antihelminth oxytocanide (Zanil, or 3,3,5,5,6-pentachloro-2,2-dihydroxybenzylidene) on *Allium cepa* roots soaked in a 0.25% soln of the agent for 2-24 hr was determined. There was a gradual decline in the mitotic index with time, with the most intense effect being observed around 24 hr. A pronounced C-mitotic effect and chromosome abnormalities were also induced. The mitotic index rose slowly and the percentage of abnormal cells decreased when the roots were allowed to recover for 24, 48, and 72 hr after an 8-hr treatment, indicating the reversibility of the genetic damage. (14 refs)

78-6256 Potential Carcinogenicity of Some Food Preservatives in the Presence of Traces of Nitrite (Meeting Abstract). (Eng) Khoudokormoff, B. (Lab. Microbial Genetics, Res. and Development, P.O. Box 1, Delft, Netherlands); Gist-Brocades, N. V. *Mutat Res* 53(2): 208-209; 1978. (no refs)

78-6257 Enhancement of Liver Microsome Epoxide Hydratase Activity in Rodents by Treatment with 2(3)-tert-Butyl-4-hydroxyanisole. (Eng) Cha, Y. N. (Dept. Pathobiology, Johns Hopkins Medical Inst., Baltimore, MD, 21205); Martz, F.; Bueding, E. *Cancer Res* 38(12): 4496-4498; 1978.

Epoxide hydratase (EH) activity was assayed in liver microsomes from female CD-1 mice fed a diet containing 0.75% of the antioxidant 2(3)-tert-butyl-4-hydroxyanisole (BHA) for 10 days. The liver microsomes were incubated with styrene oxide [200 nanomoles (nmol)], and EH activities were expressed in terms of nmol of styrene diol metabolite per mg protein per min. Three days after initiation of BHA feeding the specific activity of EH was 9.40 nmol diol/mg/protein/min, or 9 x the control value. The activity then rose more slowly, reaching 11.11 nmol/mg/protein/min at 10 days. Only two- to threefold increases in enzyme activity were induced by 3-methylcholanthrene, phenobarbital, and Aroclor 1254. When BHA (750 mg/kg/day) was administered by gastric intubation for 4 days, the increase in EH activity was 75% of that attained by dietary administration of the antioxidant. The possibility that BHA may enhance or protect against the carcinogenic effects of diol-epoxides is discussed (26 refs)

78-6258 N-Acetyl- β -glucosaminidase Activity in the Peripheral Blood WBC of Rats Subacutely Exposed to Benzene Vapor. (Pol) Starek, A. (Katedra Medycyny Pracy i Chorob Zawodowych, AM w Krakowie, 30-900 Krakow 28, Poland); Moszczynski, P. *Patol Pol* 29(1): 71-72; 1978.

The effect of a 10-day exposure to benzene vapor (6 hr/day, 27,000 mg/m³) on N-acetyl- β -glucosaminidase (AGA) activity in the peripheral blood WBC was studied in 12 male Wistar rats aged 8 mo. The exposure reduced the number of neutrophil granulocytes from 3,826/mm³ to 2,271/mm³ (p < 0.005), the AGA activity in the granulocytes from 53.8 to 16.8 units (p < 0.001), the lymphocyte count from 10,963/mm³ to 1,330/mm³ (p < 0.001), and the percentage of AGA-positive lymphocytes from 54.9% to 50.4% (p < 0.05). Within the subpopulation of AGA-positive lymphocytes, the percentage of granular-type cells decreased and that of granular-diffusion and diffusion-type cells increased. The effects are due to the damaging action of benzene on the granulocyte lysosomes and on peripheral blood lymphocytes (24 refs)

78-6259 Modified Method for Electron Capture Gas-Liquid Chromatographic Determination of Hexestrol Residues in Bovine Tissues. (Eng) Tobioka, H. (Dept. Animal Science, Coll. Agriculture, Kyoto Univ., Kyoto 606, Japan); Kawashima, R. *J Assoc Off Anal Chem* 61(5): 1054-1057; 1978.

Hexestrol residues in the tissues of cows injected with hexestrol dicaprylate were determined by electron capture gas-liquid chromatography. The method was suitable for determining residues of 0.5 ppb; the limit of sensitivity ranged from 0.1 to 0.2 ppb. (16 refs)

6260 Thiophene Analogues of the Carcinogens Benzidine and 4-Aminobiphenyl: Evaluation In Vitro.

(Eng) Ashby, J. (Central Toxicology Lab., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Styles, J. A.; Anderson, D.; Paton, D. *Br J Cancer* 38: 521-529; 1978.

Thiophene analogs of benzidine and 4-aminobiphenyl (N-acetamidophenyl-2-thiophenamine hydrochloride (XV), 5-phenyl-2-thiophenamine hydrochloride (XIX), N-p-acetamidophenylthiophen-2-yl)acetamide (XV), and N-phenylthiophen-2-yl)acetamide (XVI), were tested for mutagenicity in vitro by the Ames reverse-mutation assay and the Styles cell-transformation assay. In Ames tests with *Salmonella typhimurium* strains TA1535, TA1538, TA98, and TA100, each of the thiophenes produced at least one positive response in TA1538 or TA98, sometimes in the absence of a rat liver S-9 mix. In two runs of the Styles assay, the acetyl derivatives XV and XVI gave a positive response, while the amine hydrochlorides XIX and XVI were negative. The acetyl derivatives possessed greater cytotoxicity. It was suggested that the relative transforming abilities of these compounds is determined by the ability of XV and XVI to form DNA-reactive hydroxylamine-ester compounds and the ability of XIX and XIV to form N-hydroxy-ester compounds. (29 refs)

6261 Di-(4-aminophenyl)-methane (MDA): 4-7 Year Dog Feeding Study. (Eng) Deichmann, W. B. (National Center for Toxicology, Dept. Pharmacology, Univ. of Miami Sch. of Medicine, P.O. Box 248216, Coral Gables, FL 33124); MacDonald, W. E.; Coplan, M.; Woods, F.; and E. *Toxicology* 11(2): 185-188; 1978.

The possible carcinogenic action of purified and crude di-(4-aminophenyl)-methane (MDA) on the urinary bladder was studied in nine female beagle dogs. The compounds were given po at a dose of 70 mg/kg/day 3 x/wk for life (up to 4 yr and 2 mo). There were no significant effects on body weight except for an occasional weight loss that was followed by quick recovery after withdrawal from treatment. Results of all laboratory tests were negative except for elevated alkaline phosphatase activity in two dogs. Moderate to severe gross morphologic changes occurred in the livers of all dogs; severe changes were seen in the kidneys (4 dogs), spleens, urinary bladders (2), lungs (3), ovaries and fallopian tubes, and uterus (1). There were no tumors of the urinary bladder or liver. (3 refs)

6262 Chlorination of Benzidine and Other Aromatic Amines in Aqueous Environments. (Eng) Jensen, R. L. (County Sanitation Districts Los Angeles County, San Jose Creek Water Quality Lab., 1965 S. Workman Mill Road, Whittier, CA, 90601); Haskins, J. E.; Carmona, L. G.; and Bird, R. B. *Arch Environ Contam Toxicol* 7(3): 301-315; 1978.

Exposure of aniline, but not N,N-dimethylaniline, to chlorinated waters yielded a solid product. For these monophenyl amines, ring chlorination was a significant depletion pathway. Extended chlorination of benzidine resulted immediately in a solid product that, upon infrared analysis, was shown to be a polymeric structure with no ring chlorination. Analysis of the supernatant revealed no ring-substituted isomers of benzidine. (18 refs)

78-6263 An Improved Method for Detecting Mutagens (Meeting Abstract). (Eng) Yahagi, T. (Natl. Cancer Res. Inst., Tokyo, Japan); Nagao, T.; Matsushima, T.; Seino, Y.; Sawamura, N.; Shirai, A.; Kawachi, T.; Sugimura, T. *Mutat Res* 53(2): 285; 1978. (no refs)**78-6264 Genetic Variation in N-Acetylation of Carcinogenic Arylamines by Human and Rabbit Liver.**

(Eng) Glowinski, I. B. (Dept. Pharmacology, Univ. Michigan, Ann Arbor, MI, 48109); Radtke, H. E.; Weber, W. W. *Mol Pharmacol* 14(5): 940-949; 1978.

The arylamine carcinogens aminofluorene, α -naphthylamine, β -naphthylamine, benzidine, and methylene bis-2-chloroaniline were found to be acetylated by the same polymorphic N-acetyltransferase (NAT) as sulfamethazine (SMZ) and isoniazid (INH). Liver (0.10 ml) NATs purified from slow and fast INH-acetylating rabbits and humans were incubated with 0.05 ml aqueous radioactive acetyl coenzyme A (2×10^{-3} M) and 0.05 ml amine substrate solution. After the radioassay of acetylating activity, K_m values were determined for enzyme-substrate interactions. Rabbit liver NAT had a smaller apparent K_m than the human liver enzyme for all substrates tested except α and β naphthylamine, and reactions with carcinogenic substrates in both enzyme systems yielded K_m 's at least an order of magnitude smaller than when SMZ was the substrate. Although K_m values within a species did not change, the carcinogenic compounds showed greater differences in acetylation rates between rapid and slow acetylators than did SMZ; therefore, they appeared to be polymorphically acetylated in both rabbit and man. Octanol-water partition coefficients measured for each substrate correlated closely with the apparent K_m values for both human and rabbit NAT, supporting the hypothesis that differences in apparent K_m 's were related to the greater hydrophobicity of the carcinogens than of SMZ. Because all the carcinogens served as substrates for polymorphic NAT, hydrophobicity and differences between slow and fast acetylators could be important in determining an individual's susceptibility to arylamine carcinogenesis. 78-6265 Hepatocarcinogen-induced tRNA Methylase Activity in Rat Liver. (Eng) Forrester, P. I. (Div. Medical Biochemistry, Faculty Medicine, Univ. Cal-

gary, Calgary, Canada); Hancock, R. L. *Physiol Chem Phys* 10(2): 115-123; 1978.

Dimethylaminoazobenzene and carbon tetrachloride extend the list of hepatocarcinogens capable of increasing rat liver transfer RNA (tRNA) methylase activity. Ethionine increased this activity in rats and guinea pigs but not in chicks. Aminoazobenzene, acetylaminofluorene, α - and β -naphthylisothiocyanate, dimethyl- and diethylnitrosamine, and methylcholanthrene produced no increase or slight increases. (13 refs)

- 78-6266 **Toxicity of p-Substituted Derivatives of Aniline in Experimental Rats.** (Cze) Matrká, M. (Toxikol. Odd., Vyzkumny ustav organických syntéz, 533 51 Pardubice-Rosice, Czechoslovakia); Rambousek, V.; Zverina, Z. *Cesk Hyg* 23(4): 168-172; 1978.

The acute po toxicity of aniline and six of its substituted derivatives was determined in male Wistar rats. The substances were administered in soln or in an olive oil suspension. The LD₅₀ values were 0.440 mg/kg for aniline (A), 0.417 mg/kg for 4-fluoroaniline (FA), 0.370 mg/kg for 4-chloroaniline (CA), 0.456 mg/kg for 4-bromoaniline (BA), 0.523 mg/kg for 4-iodoaniline (IA), 0.794 mg/kg for 4-methylaniline (MA), and 0.750 mg/kg for 4-nitroaniline (NA). The mole LD₅₀ values were 0.00265 (BA), 0.00239 (IA), 0.00755 (MA), and 0.00543 (NA). Hammett's σ constants were 0 (A), +0.06 (FA), +0.23 (CA and BA), +0.27 (IA), -0.17 (MA), +0.78 (NA). A good correlation was seen between the mole LD₅₀ values and Hammett's constants. The six aniline derivatives represent the last biotransformation step of the corresponding carcinogens derived from 1-phenyl-3,3-dimethyltriazene. (16 refs)

- 78-6267 **Metabolism-mediated Cytotoxicity of Chemical Carcinogens and Non-carcinogens.** (Eng) Wiebkin, P. (Inst. Industrial, Environmental Health and Safety, Univ. Surrey, Guildford, Surrey GU2 5XH, England); Fry, J. R.; Bridges, J. W. *Biochem Pharmacol* 27(14): 1849-1851; 1978.

The general applicability of a mixed cell culture system in assessing the importance of metabolism in chemically mediated cytotoxicity was tested using carcinogenic and noncarcinogenic chemicals. Rat fibroblasts were incubated with at least five concentrations of each test compound for 1 hr at 37 C in the presence or absence of viable rat hepatocytes. The samples were then diluted and cultured at 37 C for 6-8 days, after which time counts of nuclei were performed and the results calculated as ID₅₀ values; i.e., the concentration of the chemical that inhibited fibroblast growth by 50%. In the presence of hepatocytes, the most toxic pair of compounds tested was 3'-methyl-4-dimethylaminoazobenzene (3'-methyl-DAB; ID₅₀, 0.1 μ g/ml) and 2-methyl-4-dimethyl-

aminoazobenzene (2-methyl-DAB; ID₅₀, 2.0 μ g/ml). In the absence of hepatocytes, the ID₅₀ values for 3'-methyl-DAB and 2-methyl-DAB were > 125 and > 250 μ g/ml, respectively. Mitomycin C also required hepatocyte metabolism for its cytotoxicity to be fully expressed, but hepatocyte metabolism decreased the cytotoxicity of 4-nitroquinoline-1-oxide. Other compounds that showed increased cytotoxicity in the presence of hepatocytes were cyclophosphamide, dimethylnitrosamine, 2-acetylaminofluorene, 4-acetylaminofluorene, 6-aminochrysene, and 2-aminochrysene. - 78-6270 **Liver and Urinary Bladder Tumors in Dogs from 3,3'-Dichlorobenzidine.** (Eng) Stula, E. (Haskell Lab., Elkton Road, Newark, DE, 19711); Barnard, J. R.; Sherman, H.; Reinhardt, C. F.; Zapp, J. A. *J Environ Pathol Toxicol* 1(4): 475-490; 1978.

The carcinogenic effects of po 3,3'-dichlorobenzidine (DCB) were studied in six female beagle dogs. DCB was given at a rate of 100 mg 3x/wk for 6 wk, then 5x/wk for up to 7.1 yr. Untreated controls were sacrificed after 8.3-9.0 yr. All DCB-treated dogs showed elevated plasma glutamic-pyruvate transaminase activity during the first 3 yr, and two dogs showed elevated activity throughout the test. One DCB dog sacrificed in extremis after 3.5 yr, had no tumors. Another dog sacrificed in extremis after 6.6 yr, had an undifferentiated carcinoma of the liver with metastases to many organs and a papillary transitional cell carcinoma of the urinary bladder. Three of the remaining four dogs sacrificed after 7.1 yr had hepatocellular carcinomas, and all four had transitional cell carcinomas of the urinary bladder. There were no such tumors in the control dogs. The data indicate that DCB is carcinogenic for the liver and urinary bladder in the dog and that in this species, it is more carcinogenic than benzidine. (1 refs)

- 78-6271 **Mutagenicity of Pesticides in Blue-Green Algae.** (Eng) Das, B. (Lab. Blue-Green Algae)

tral Rice Res. Inst., Cuttack 753006, Orissa, India);
gh, P. K. *Microbios Lett* 5(19/20): 103-107; 1977.

e mutagenicity of hexachlorocyclohexane (BHC) and
dichlorophenoxyacetic acid (2,4-D) to four blue-green al-
(3 N-fixing, 1 non-N-fixing) was investigated. A slight
crease in mutation frequency was noticed after treatment
h BHC, but 2,4-D treated cultures did not show any in-
ase. The results suggest that BHC is a weak mutagen for
e-green algae, whereas 2,4-D is nonmutagenic. (19 refs)

6272 **The Mutagenicity of Substituted and Unsub-**
stituted Styrene Oxides in *E. coli*: Relationship
between Mutagenic Potencies and Physico-chemical Proper-
ties. (Eng) Sugiura, K. (Inst. Ecotoxicology, Gakushuin
iv., Toshima-ku, Tokyo 171, Japan); Yamanaka, S.;
kasawa, S.; Goto, M. *Chemosphere* 7(9): 737-742; 1978.

e relationship between the mutagenic potencies and
physicochemical properties of substituted and unsubstituted
styrene oxides was studied. 3,4-Dimethylstyrene oxide was
most lethal to *Escherichia coli* strain WP100 and more muta-
genic in strains WP100 and CM571 than in strains WP2uvrA
and WP2. Styrene oxide had similar lethal and mutagenic
effects. These results indicate that the uvrA and recA genes
affect both the lethal and mutagenic responses. The
mutagenicity and lethality of these and other compounds in-
creased in the order: m-methoxystyrene oxide < styrene ox-
ide < p-methylstyrene oxide < m-methylstyrene oxide <
3,4-dimethylstyrene oxide < m-chlorostyrene oxide <
bromostyrene oxide. In reactions of substituted styrene ox-
ides with nucleophiles, the normal reaction rate was higher
with electron-withdrawing substituents and lower with elec-
tron-releasing substituents. In contrast, the rate of abnormal
reactions (attack at CH) was higher with electron-releasing
substituents. The relative LD₅₀ values of the styrene oxide
derivatives agreed with the relative partition coefficients, sug-
gesting that the rate of transport of styrene oxides to their
molecular sites of action is the rate-limiting condition. The data
demonstrate that the mutagenic effect of a chemical may vary
with the structure of its products. (11 refs)

6273 **Pathology of Esophageal Neoplasms and As-**
sociated Proliferative Lesions Induced in Rats
by N-Methyl-N-benzyl nitrosamine. (Eng) Stinson, S. F. (Tu-
mor Pathology Branch, Div. Cancer Cause and Prevention,
NCI, NIH, Public Health Service, U.S. Dept. Health, Educa-
tion and Welfare, Bethesda, MD, 21205); Squire, R. A.;
Barn, M. B. *J Natl Cancer Inst* 61(6): 1471-1475; 1978.

After receiving 20 weekly sc injections of N-methyl-N-ben-
zyl nitrosamine (MBZN: 2.5 mg/kg), 24 inbred male F344
rats developed 194 lesions of the upper gastrointestinal tract.

Grossly, most lesions were exophytic; 74% were pedun-
culated papillary growths and the remainder were sessile pro-
liferations. Localized elevated thickening of the esophageal
wall was observed in 20% of the rats. All rats developed
papillomas, 63% developed carcinomas that invaded the eso-
phageal wall, and 67% developed pedunculated papillary car-
cinomas. Of the esophageal tumors, 66% were papillomas,
17% were pedunculated papillary carcinomas, and 17% were
invasive carcinomas. The papillomas were pedunculated
(87%) or sessile (13%). The carcinomas that invaded the
esophageal wall were sessile (78%) or infiltrating (22%). All
neoplasms were well-differentiated squamous cell tumors,
with varying degrees of keratinization. Although penetration
through the esophageal wall was common, no metastases
were seen. No primary lesions were seen in sites other than
the esophagus and pharynx. These tumors were similar mor-
phologically to human specimens. Therefore, the usefulness
of this model in the study of human esophageal carcinoma
is indicated. (11 refs)

78-6274 **The Role of Glutathione in Experimental**
Chemical Hepatocarcinogenesis. (Eng) Fiala, S.
(Cell Physiology Lab., VA Center, Martinsburg, WV); Trout,
E. C.; Kettering, W. G. In: *Prevention and Detection of Can-*
cer. Proceedings of the Third International Symposium on De-
tection and Prevention of Cancer Held by the International
Study Group for the Detection and Prevention of Cancer in
New York, April 26 - May 1, 1976. International Study Group
for the Detection and Prevention of Cancer. (New York,
NY): Vol. 2(Part 1), 2404 pp.; 1291-1304; 1978.

The behavior of glutathione (GSH) in rat liver during azo
dye-induced carcinogenesis was investigated to determine
whether hepatocarcinogenesis is due to inhibited and disrupt-
ed differentiation of stem cells. The concentration of GSH
in fetal and neonatal liver was 110 and 140 mg/100 g, respec-
tively, vs 234 mg/100 g in adult liver. Following administra-
tion of 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB;
33 mg), there was a small initial decrease in liver GSH due
to its conjugation with some of the azo dye metabolites and
its elimination in bile. This was followed by a rapid increase
in GSH synthesis as early as 8 hr after 3'-Me-DAB adminis-
tration. In later stages of hepatocarcinogenesis, γ -glutamyl-
transpeptidase (GT-ase) activity was very high, resulting in
rapid degradation of GSH. The liver of hypophysectomized
rats, which do not develop hepatomas as a result of azo dye
administration, did not form GSH conjugates and did not
have increased GSH or GT-ase activity. GSH, being nucleo-
philic, may combine with and protect against various electro-
philic metabolites. Even with an excess of carcinogen, the
hepatocyte seems to be largely immune to electrophilic attack
because the initial GSH depletion is overcompensated by its
increased rate of synthesis. The mature hepatocyte, therefore,
does not appear to be the target of proximate carcinogens.
A fetal-like hepatic stem cell with high GT-ase activity may
be the actual carcinogen-sensitive cell. (27 refs)

- 78-6275 Inhibition of 3'-Methyl-4-dimethylaminoazobenzene-induced Hepatocarcinogenesis by Portacaval Shunt.** (Eng) Fiala, S. (Cell Physiology Lab., Veterans Admin. Center, Martinsburg, WV, 25401); Pragani, B.; Reuber, M. D. *Tumori* 64(2): 131-142; 1978.

Adult male Sprague-Dawley rats who underwent an end-to-side portacaval shunt (PCS) did not develop hyperplastic nodules and hepatomas when they were fed 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB) in a semisynthetic basal diet for up to 169 days. In contrast, all intact rats fed the same diet for only 75 days developed hyperplastic nodules. Following transfer to a normal diet for another 25 days, hepatomas developed in 100% of these animals. The amount of protein-bound 3'-Me-DAB and the glutathione (GSH) level was lower in operated rats than in intact controls. A single large dose of 3'-Me-DAB (10 mg/100 g) increased the GSH concentration by only 30% after 24-48 hr, compared with an increase of 50%-100% in intact rats. There was no gradual increase in the activity of γ -glutamyltranspeptidase (GTase) in operated rats during 5.5 mo of 3'-Me-DAB feeding. The increase in GTase activity was never > 30% higher than the level in livers of operated rats fed a basal diet without the carcinogen. This striking inhibition of GTase activity induced by 3'-Me-DAB in PCS-operated rats contrasted with a 5,000% increase in enzyme activity found in the livers of intact rats with hyperplastic nodules after 75 days of 3'-Me-DAB feeding and with the up to 10,000% increase in the hepatomas. These effects and the inhibition of 3'-Me-DAB-induced hepatocarcinogenesis, manifested by a lack of preneoplastic morphologic changes and the absence of hepatomas in rats after PCS, can best be explained by a functional deficiency of the liver to metabolize the procarcinogen 3'-Me-DAB to an activated carcinogen. (25 refs)

- 78-6276 A Study of Cyclic Nucleotide Metabolism and the Histology of Rat Liver During 3'-Methyl-4-dimethylaminoazobenzene Carcinogenesis. I. Histology.** (Eng) Boyd, H. (Dept. Pharmacology, Univ. Miami Sch. Medicine, Miami, FL, 33152); Hensley, G. T. *Tissue Cell* 10(3): 463-476; 1978.

Male Sprague-Dawley albino rats were fed 3'-methyl-4-dimethylaminoazobenzene (3'-MeDAB) ad libitum in pellets (0.06% in 0.75% corn oil) for 12 wk, and their livers were examined histologically at weekly intervals up to 13 wk. The first tumor mass was noted at 4 wk and there was a 100% incidence of cholangiocarcinomas by 10 wk. Acidophilic hepatocytes that appeared in periportal regions of liver lobules at 3 wk were smaller than normal and glycogen-deficient. After 4 wk, even smaller glycogen-deficient cells with a large nucleus/cytoplasm ratio appeared. These small cells and the acidophilic cells underwent mitosis, and there was no indication of acute or chronic inflammation or fibrosis. By 7 wk, the small cells became increasingly organized into ductular structures that were composed of columnar epithelial cells and mucous-secreting goblet cells. Proliferating epi-

thelial cells were frequently associated with necrosis and destruction of the parenchyma. Tissue that appeared to be uninvolved to the naked eye often contained 50% unorganized small cells. In this study, no hepatocellular carcinoma developed by 13 wk. (42 refs)

- 78-6277 Pre-tumor Phase Serum Alpha-Fetoprotein and Its Molecular Variants During Hepatocarcinogenesis.** (Eng) Nadworny, H. A. (Dept. Medicine, Univ. Vermont Coll. Medicine, Burlington, VT, 05401); Smith, C. Kelleher, P. C. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY) Vol. 2(Part 1), 2404 pp.; 1283-1290; 1978.

Radial immunodiffusion was used to monitor the weekly serum alpha-fetoprotein (AFP) concentrations in 39 Fischer 344 rats that were fed 0.063% 3'-methyl-4-dimethylaminoazobenzene (3'-Me-DAB) in the diet beginning at 6 wk of age. Serum AFP levels were undetectable (< $\mu\text{g/ml}$) at 6 wk of age. AFP was detectable in the serum of 30/39 rats after 3 wk of 3'-Me-DAB intake and in all surviving rats after 6 wk of intake. This first elevation of pre-tumor phase serum AFP lasted until 7 wk after the start of the diet and was followed by a second elevation starting at 10-11 wk in 35/36 rats and lasting for 4-6 wk. Max serum AFP concentrations during each period of increase varied widely among the individual rats (12-700 $\mu\text{g/ml}$ in the first period, 20-220 $\mu\text{g/ml}$ in the second). The percentages of total pre-tumor phase serum AFP not reactive with concanavalin A showed no consistent pattern either within an individual animal (14%-51%) or among individuals (11%-51%). The mechanisms responsible for the cyclic elevations of pre-tumor phase serum AFP are not known. (13 refs)

- 78-6278 Mechanisms of Immunosuppression Induced in Mice by o-Aminoazotoluene and Its Noncarcinogenic Analog.** (Rus) Kaledin, V. I. (Lab. Cancer Genetics, Inst. Cytology and Genetics, Siberian Branch, Acad. Sciences USSR, Novosibirsk, USSR); Glazko, T. T.; Krasovskiy, P. M.; Chesnokova, V. M. *Vopr. Onkol* 24(9): 46-52; 1978.

The immunosuppressive effects of single ip doses of o-aminoazotoluene (OAT: 4.5 mg) or its noncarcinogenic analog aminoazobenzene (AAB: 4 mg) were studied in male DD mice inoculated im with 10^6 Krebs-2 carcinoma cells. When OAT and AAB were administered 24 hr before tumor transplantation, tumor wts at the end of the experiment were 0.68 and 0.9 g, respectively, vs 0.55 g in controls. When OAT and AAB were injected 72 hr before tumor graft, tumor wts were 1.36 and 1.26, respectively, vs 0.91 g in controls. Immunization of the mice with irradiated (10,000 rads) tumor cells

ngly inhibited the growth of the implanted tumor, but the or wt was 3-3.5 times higher in the immunized and OAT-AAB-treated animals than it was in immunized animals out OAT or AAB treatment. The findings indicate the ly pronounced immunosuppressive effect of OAT and B. The immunosuppressive effect of AAB was due to its phocytotoxicity, whereas the effect of OAT was mediated the adrenal gland. After OAT injection, the serum oxycorticosteroid level was elevated, although production his hormone by the adrenal glands was not increased. The umulation of glucocorticoids in serum after OAT injection elieved due to reduced hormone utilization because of a ck of receptor proteins or metabolizing hepatic enzymes the carcinogen. (12 refs)

6279 **The Generation of Aerosols of Carcinogenic Aromatic Amines.** (Eng) Rappaport, S. M. (Sch. blic Health, Univ. California, Berkeley, CA, 94720); ttemy, D. J. *Am Ind Hyg Assoc J* 39(4): 287-294; 1978.

he development of an aerosol generator for the production test atmospheres of carcinogenic aromatic amines is de-ribed. The generator, a compressed-gas nebulizer, operates a temperature above the melting point of the test com-unds and uses nitrogen as a driving force. The nebulizer tput and size distributions of aerosols of 4,4'-me-ylenebis(2-chloroaniline), benzidine, and 3,3'-dichloroben-dine are given. The apparatus is capable of continuous oper- on over a minimum of 8 hr. (13 refs)

8-6281 **Absorption of Saccharin from Rat Urinary Bladder (Letter to Editor).** (Eng) Colburn, W. . (Dept. Biochemistry and Drug Metabolism, Hoffmann-La Roche, Inc., Nutley, NY, 07110). *J Pharm Sci* 67(10): 493-1494; 1978.

Measurements of plasma levels of saccharin following in vivo nstillation of 10 µg or 1 or 100 mg/kg of the compound into he urinary bladder of male Sprague-Dawley rats showed that his substance was absorbed extensively from the bladder. nificant reabsorption may decrease the elimination rate for accharin in much the same way as enterohepatic cycling and probably accounts for the retention of saccharin in urinary ladder tissue. (3 refs)

78-6282 **Saccharin Inhibits Guanylate Cyclase Activity: Possible Relationship to Carcinogenesis.** (Eng) Vesely, D. L. (Dept. Medicine, Univ. Miami Sch. Medicine, Miami, FL, 33152); Levey, G. S. *Biochem Biophys Res Com- mun* 81(4): 1384-1389; 1978.

The effect of saccharin (2,3-dihydro-3-oxobenzisul- fonazole) on guanylate cyclase activity was tested in a variety of tissues obtained from male Sprague-Dawley rats. Saccha- rin significantly inhibited guanylate cyclase in urinary blad- der, liver, stomach, colon, and kidney tissues over the concen- tration range 16-160 mM. Maximum inhibition was 60%-75%. The concentrations of saccharin decreasing gua- nylate cyclase activity in the in vitro rat urinary bladder assay (approx 3 to 9 mg/ml) were well within the range of concen- tration which can be obtained in urine of persons who use low calorie soft drinks and sugar substitutes and therefore interact in vivo with bladder tissue. The saccharin used in this study was synthesized by the Maumee process and contained no detectable amounts of o-toluenesulfonamide, the impurity most often associated with cancer. It is concluded that the question of saccharin carcinogenicity in man must be serious- ly studied regardless of its mode of synthesis. (29 refs)

78-6283 **Enhancement of Oncogenesis in C3H/10T1/2 Mouse Embryo Cell Cultures by Saccharin.** (Eng) Mondal, S. (Comprehensive Cancer Center, Univ. Southern California, Los Angeles, CA, 90033); Brankow, D. W.; Heidelberger, C. *Science* 201(4361): 1141-1142; 1978.

The transforming and promoting activities of saccharin were studied in vitro using C3H/10T1/2, clone 8, mouse embryo fibroblasts. At 2 mg/ml, saccharin alone was nontoxic and nontransforming, and it had no initiating effect when fol- lowed 4 days later by continuous treatment with 12-O-tet- radecanoylphorbol-13-acetate (TPA). However, both pure and impure samples of saccharin (100 µg/ml) showed signifi- cant cocarcinogenic activity during continuous treatment of cultures initiated with 3-methylcholanthrene (0.1 µg/ml). TPA, but not saccharin, promoted UV-initiated cells. The reason for this difference between these otherwise equivalent initiators is not clear. Nevertheless, the results suggest that saccharin acts as a promoter and that caution should be ap- plied to the indiscriminate or long-term use of saccharin in human nutrition. (22 refs)

78-6284 **Cytogenetic Hazards from Fensulfothion, Dex- on (DAPA) and its Degradation Product, Dime- thylphenylene Diamine (DMPDA) (Meeting Abstract).** (Eng) Panda, B. B. (Cytogenetics Lab., Berhampur Univ., Berhampur 760 007, India); Sahu, R. K.; Sharma, C. B. *Mutat Res* 53(2): 247-248; 1978. (no refs)

- 78-6286 **Carcinogenicity of o-Aminoazotoluene in Mouse Intestine.** (Rus) Kaledin, V. I. (Lab. Cancer Genetics, Inst. Cytology and Genetics, Siberian Branch, Acad. Sciences USSR, Novosibirsk, USSR); Alekseeva, G. V.; Volkova, A. I. *Biull Eksp Biol Med* 86(10): 476-477; 1978.

The carcinogenicity of o-aminoazotoluene (OAT) was studied in 60 2-mo-old male A/He mice. OAT was implanted under the skin in 8 doses of 10 mg each at monthly intervals (total dose, 80 mg). All animals died 435 ± 13 days after the first implantation. Liver tumors were the principal cause of death, but 19/60 animals also developed intestinal tumors localized exclusively to the cecum. These tumors were identified as adenomas or muciparous adenocarcinomas. According to the literature, A/He mice do not develop spontaneous intestinal tumors, and in previous experiments with CC57BR, C57BL/6, C3H/He, and DD mice treated with OAT in the same manner, intestinal tumors failed to develop. The genetic basis for the sensitivity of the cecal tissue of A/He mice to OAT is unknown. (2 refs)

- 78-6287 **Mutagenicity of Chlorinated Phenoxyacetic Acids in *Saccharomyces cerevisiae* (Meeting Abstract).** (Eng) Zetterberg, G. (Dept. Genetics and Plant Breeding, Univ. Uppsala, S-750 07, Uppsala, Sweden). *Mutat Res* 53(2): 285-286; 1978. (2 refs)

- 78-6288 **Case Control Study: Malignant Mesenchymal Soft-Tissue Tumors and Exposure to Phenoxy Acids or Chlorophenols (Letter to Editor).** (Swe) Sandstrom, A. (Umea, Sweden) *Lakartidningen* 75(40):

Fifty-two men, aged 26-80 yr, with malignant mesenchymal soft-tissue tumors and 206 matched controls were surveyed by questionnaire for past occupational exposure to 2,4-dichlorophenoxyacetic acid (2,4-D) and/or 2,4,5-trichlorophenoxyacetic acid (2,4,5-T). The incidence of past exposure was 19/52 among the tumor patients vs 19/206 among the tumor-free controls. This difference was statistically significant ($p < 0.001$). It was not possible to evaluate the risks of 2,4-D and 2,4,5-T separately, because most patients may also have been exposed to other chemicals, such as tetrachlorodibenzodioxin. These findings suggest that exposure to phenoxy acids, chlorophenols, and/or their impurities increases the risk of soft tissue tumors. (5 refs)

- 78-6289 **The Chemistry of Phenalenium Systems. XX. Novel Ring Contraction During m-Chlorobenzoic Acid Oxidation of Mutagenic Azuleno[1,2,3-cd]phenalene. A Model for Metabolic Activation and Binding of Mutagenic Nonalternant Hydrocarbons.** (Eng) Nakasuji, K. (Dept. Chemistry, Faculty Science, Osaka Univ., Toyonaka, Osaka 560, Japan); Nakamura, Murata, I. *Tetrahedron Lett* (18): 1539-1542; 1978.

The reaction of m-chloroperbenzoic acid with azuleno[1,2,3-cd]phenalene (AP), a highly mutagenic, nonalternant isomer of benzo(a)pyrene, was investigated. The products formed were 11-oxo-11H-benzo[cd]fluoranthene and 1-oxo-1H-benzo[cd]fluoranthene. This reaction may provide a model for the mutagenic and carcinogenic activity of AP. (13 refs)

- 78-6290 **Screening of Safrole, Eugenol, Their Ninhydrin Positive Metabolites and Selected Secondary Amines for Potential Mutagenicity.** (Eng) Green, N. (Dept. Food and Nutrition, Coll. Home Economics, Florida State Univ., Tallahassee, FL, 32306); Savage, J. R. *Mutat Res* 57(2): 115-121; 1978.

The mutagenicity of safrole (4-allyl-1,2-methylenedioxybenzene), eugenol, the secondary amines with which they combine during metabolism, and the ninhydrin positive urinary metabolites of safrole and eugenol was tested in the direct bacterial assay, a microsomal mutagenesis assay (MMA), and a host-mediated assay. In the direct bacterial assay, in which four mutant strains of *Salmonella typhimurium* (TA1538, TA1531, TA1532, and TA1964) were used, all the compounds gave negative results. With the same four mutant strains, safrole and its metabolite 3-piperidyl-1-(3',4'-methylenedioxyphenyl)-1-propanone were mutagenic with strains TA1530 and TA1532 in the MMA and with strains TA1950 and TA1952 in the host-mediated assay. Dimethylamine was a weak mutagen in the MMA with strain TA1538. Negative results were obtained for the safrole metabolites 3-N,N-dimethylamino-1-(3',4'-methylenedioxyphenyl)-1-propanone and 3-pyrrolidinyl-1-(3',4'-methylenedioxyphenyl)-1-propanone, eugenol, the eugenol metabolites 3-piperidyl-1-(3'-methoxy-4'-hydroxyphenyl)-1-propanone and 3-pyrrolidinyl-1-(3'-methoxy-4'-hydroxyphenyl)-1-propanone, piperidine, piperidine acid, proline, and pyrrolidine in all three assay systems. These results suggest that the MMA is more sensitive than the host-mediated assay. (16 refs)

- 78-6291 **Conversion of the N-O-Glucuronide and N-O-Sulfate Conjugates of N-Hydroxyphenacetin to Reactive Intermediates.** (Eng) Mulder, G. J. (Lab. Chemical Pharmacology, Natl. Heart, Lung and Blood Institute, NIH, Bethesda, MD, 20014); Hinson, J. A.; Gillette, J. *Biochem Pharmacol* 27(12): 1641-1649; 1978.

stability and reactions of the reactive intermediates formed from phenacetin (PA) N-O conjugates were studied. N-O-glucuronide of ^{14}C -acetyl-N-hydroxy-PA is sufficiently stable for it to be purified but slowly degrades in aqueous solution to a reactive intermediate that can covalently bind to protein. Several lines of evidence are given that indicate the major chemically reactive intermediate formed from glucuronidation of N-hydroxy-PA is the deethylated reactive, N-acetylimidoquinone. However, the data suggest the formation of PA and 2-hydroxy-PA glucuronide occurs by different mechanisms. The N-O-sulfate of ^{14}C -acetyl-N-hydroxy-PA also breaks down to a reactive intermediate that has properties similar to those of the reactive intermediate formed from the N-O-glucuronide and thus may also be N-acetylimidoquinone. In contrast, the relative ability of various nucleophiles to prevent the covalent binding of the reactive intermediate formed from the N-O-sulfate of N-acetylaminofluorene to protein differs from the relative ability of the nucleophiles to prevent the covalent binding of the reactive intermediate of the N-O-sulfate or the N-O-glucuronide of PA, suggesting that the relative rates at which these intermediates combine with the different macromolecules may differ markedly. These studies may be relevant to other pathways of activation of PA and acetaminophen. Although the mechanism of PA-induced nephrotoxicity is not known, it seems plausible that PA N-O-glucuronide may play a role, since it would be produced primarily in the liver and concentrated in the kidney. Its conversion to a reactive intermediate, possibly accelerated by the low pH of urine, could lead to covalent binding and the renal tubular damage associated with PA abusers. (22 refs)

78-6292 **Benzo(a)pyrene Metabolism and Plasma Elimination Rates of Phenacetin; Acetanilide and Theophylline in Man.** (Eng) Kellermann, G. (Dept. Human Toxicology, Univ. Wisconsin Medical Sch., Madison, WI); Layten-Kellermann, M. *Pharmacology* 17(4): 191-200; 1978.

The plasma elimination rates of phenacetin (PA), acetanilide (AA), and theophylline (TP) were determined in 34 healthy subjects in a search for drugs whose metabolism and regulation might resemble those of benzo(a)pyrene (BP). The plasma half-lives of PA ranged from 32.0 to 88.2 min, those of AA from 70.5 to 186.5 min, and those of TP from 5.1 to 10.4 min. The metabolic clearance rate of PA varied from 11.6 to 144.9 liters/hr, of AA from 7.5 to 18.2 liters/hr, and of TP from 55.8 to 117.0 ml/hr. Statistically significant correlations were found between (a) the half-lives of PA, AA, and TP and the metabolic clearance rates of AA and TP, and (b) the inducibility of aryl hydrocarbon hydroxylase in mitogen-stimulated lymphocytes; the metabolic clearance rates of AA did not correlate. Correlations of the three drugs with the half-lives and metabolic clearance rates of antipyrine (determined previously) were equally good. In previous studies, antipyrine metabolism correlated best with BP metabolism. In this study, antipyrine half-lives and metabolic clearance rates were most closely correlated with TP half-lives and

clearance rates. The high correlations between antipyrine and PA half-lives contrast with the findings of other studies. (54 refs)

78-6293 **Analgesic Nephropathy and Transitional Cell Carcinoma.** (Eng) Moshakis, V. (Queen Mary's Hosp. for East End, West Ham Lane, Stratford, London E15 4SD, England); Hooper, A. A. *Postgrad Med J* 54(630): 285-286; 1978.

A transitional cell carcinoma of the kidney was found in a 42-yr-old woman who had taken an average of six Codeine compound tablets daily since age 13. This represented a total of 14 kg phenacetin over 26 yr. (4 refs)

78-6294 **Long-Term Safety Evaluation and Metabolism of o-Benzoin Sulfimide (Saccharin) in Rhesus Monkeys.** (Eng) Coulston, F. (Inst. Comparative and Human Toxicology, Albany Medical Coll., Albany, NY, 12208); McChesney, E.; Benitz, K. F. *Ecotoxicol Environ Saf* 2(1): 33-48; 1978.

The results of a 79-mo safety evaluation of saccharin in 7 male and 7 female monkeys are reported. Saccharin was administered by stomach tube 6 days/wk at daily doses of 20 mg/kg (4 animals), 100 mg/kg (4 animals), and 500 mg/kg (6 animals). Six monkeys of comparable age and wt served as controls. Although there were five deaths, one in each treatment group and two in the control group, none of the deaths was related to saccharin intake. The dose regimens had no effect on animal growth or on serum biochemical or whole blood hematological parameters. At necropsy, the only lesions detected grossly or microscopically occurred as frequently in controls as in any of the treated groups. Moreover, the suspected target organ, the urinary bladder, was free of lesions in all groups. Metabolic experiments demonstrated that saccharin was eliminated rapidly (estimated half-life of 9.5 hr), mostly in the urine, and in at least 98% unchanged form. It is concluded that the no-effect level of saccharin for the rhesus monkey exceeds 500 mg/kg/day, a dose that, on a wt basis, is 50 times the recommended max daily human intake. (31 refs)

78-6295 **Effect of DNA Repair Modifying-Factors and Tumor-Promoting Agents on Mutagenesis in a Mammalian Cell Culture System.** (Eng) Lankas, G. R. (Univ. Cincinnati, Cincinnati, OH, 45221). *Diss Abstr Int B* 39(5): 2203-2204; 1978. (no refs)

78-6296 **Aryl Hydrocarbon Hydroxylase Induction in an Insect, *Spodoptera eridania* (Cramer), by Poly-**

chlorinated Biphenyls (PCBs). (Eng) Anderson, R. S. (Donald S. Walker Lab., Sloan-Kettering Inst. Cancer Res., 145 Boston Post Road, Rye, NY, 10580). *Comp Biochem Physiol [C]* 60(1): 51-55; 1978.

Commercial polychlorinated biphenyl (PCB) preparations were tested for their ability to induce aryl hydrocarbon hydroxylase (AHH) activity in terminal instar southern armyworm (*Spodoptera eridania*) midgut homogenates or microsomes. The preparations included Capacitor 21, Aroclor 1016, Aroclor 1242, Aroclor 1254, and several PCB-containing immersion oils. Topical application of PCB's in doses of 2-3 mg induced significant AHH activity, as measured by increased ¹⁴C-benzo(a)pyrene substrate metabolism. The induction levels were not proportional to the chlorine content of a given PCB compound. Max induction occurred 24 hr after exposure, and the effect persisted for at least 4 days after a single application of Aroclor 1254. *Spodoptera* homogenate and protein concentrations did not increase within 48 hr of treatment, which suggested that AHH induction by PCB's precedes proliferation of the smooth endoplasmic reticulum. (20 refs)

78-6297 Effect of Intestinal Microflora on 3,2'-Dimethyl-4-aminobiphenyl-induced Carcinogenesis in F344 Rats. (Eng) Reddy, B. S. (Naylor Dana Inst. Disease Prevention, American Health Foundation, 1 Dana Rd., Valhalla, NY, 10595); Watanabe, K. *J Natl Cancer Inst* 61(5): 1269-1271; 1978.

The effect of intestinal microflora on colon and breast cancer induced by 3,2'-dimethyl-4-aminobiphenyl (DMAB) was studied in germfree (22 male, 22 female) and conventional (30 male, 30 female) F344 rats. At 7 wk of age, all animals were started on a series of DMAB injections (100 mg/kg/wk x 20, sc). Females were autopsied at 10 wk, males at 15 wk. Tumors were induced in the colons (24/60), duodena (20/60), breasts (24/30 females), ear ducts (9/60), salivary glands (6/60), and skin (36/60) of conventional rats and in the colons (9/44), breasts (9/22 females), ear ducts (6/44), salivary glands (10/44), and skin (4/44) of germfree rats. There was no consistent difference in the incidence of ear duct, salivary gland, and skin tumors between the germfree and conventional rats. However, none of the germfree rats had duodenal tumors, and the incidence of colon and breast cancer was lower in germfree than in conventional rats. In conventional rats, both bacterial and mucosal β -glucuronidase is involved in hydrolyzing the glucuronide conjugate of DMAB, whereas in germfree rats, only mucosal β -glucuronidase is involved. This might explain the difference in colon cancer susceptibility. The possibility that the lower incidence of DMAB-induced colon and breast cancer in germfree rats might be due to their lower hepatic levels of DMAB-metabolizing enzymes cannot be ruled out. (19 refs)

78-6298 A Sequential Screening of the Cytogenetic Damage Induced by Triaziquone. (Eng) Oud, J.

L. (Inst. Genetics, Univ. Amsterdam, Kruislaan 318, Amsterdam, Netherlands); Peters, P. W. *Mutat Res* 54(1): 175-184; 1978.

The suitability of six in vivo cytogenetic tests for determining chromosome damage and the mutagenicity of the alkylating agent triaziquone (TAQ) in young adult random-bred Swiss/RIV mice was determined. The mice were inoculated either once or twice (24-hr interval) with 0.125 mg/TAQ. Two injections increased the number of aberrations considerably in both the micronucleus test and the bone marrow metaphase test, but not in the spermatocyte translocation test or the spermatogonial metaphase test. In the latter, a strong cell-killing effect of TAQ was noted. Analysis of whole mounts of seminiferous tubules showed that 0.125 mg/kg was a lethal dose for all B- and intermediate-type spermatogonia and partly killed A-type spermatogonia. A single dose caused stable chromosome rearrangements in spermatids that could be demonstrated with the F₁ translocation test, and it gave rise to dominant lethality of fetuses originating from postmeiotic sperm. The micronucleus test, the results of which are similar to those of the bone marrow test, is concluded to be a reliable and easy screening method for chromosome aberrations in vivo. The spermatogonial metaphase test can be used to determine the capability of a compound to reach germ cells in seminiferous tubules. The spermatocyte translocation test is informative about stable aberrations in a permanent cell type, and the F₁ translocation and dominant lethal tests reveal the induction of inheritable chromosome rearrangements in spermatids and spermatozoa. 78-6299 Carcinogenic Compounds: Synthesis of Polycyclic Carbazole Derivatives by Diels-Alder Reaction. (Eng) Hiremath, S. P. (Dept. Chemistry, Karnataka Univ. Post Graduate Centre, Gulbarga-585 105, India); Kaddargi, S. S.; Purohit, M. G. *J Indian Chem Soc* 55(2): 156-157; 1978.

Polycyclic benzocarbazoles were synthesized by Diels-Alder reaction of 3-(β -nitrovinyl)benz(e)indole with various dienophiles such as 1,4-benzoquinone, 1,4-naphthoquinone, N-phenylmaleimide, dimethyl acetylenedicarboxylate, and tetracyanoethylene. These compounds are structurally similar to polycyclic hydrocarbons, and they have shown carcinogenic activity. (13 refs)

78-6300 The Tumor-producing Effect of Automobile Exhaust Condensate and Fractions Thereof. Part 1: Chemical Studies. (Eng) Grimmer, G. (Biochemisches Institut für Umweltcarcinogene, Sieker Landstrasse 19, 2070 Ahrensburg, W. Germany); Bohnke, H. *J Environ Pathol Toxicol* 1(5): 661-667; 1978.

A detection system designed to discriminate between the carcinogenic and noncarcinogenic fractions of a mixture must

onstrate the following: (1) a reproducible dose/effect relation of the carcinogen over a large range; (2) additive effects of two or more carcinogens; and (3) no or negligible influence of large amounts of ineffective substances on the carcinogenicity of the carcinogen in a complex mixture. The key for the detection of all carcinogens from a complex mixture and the estimation of their efficiencies is a suitable animal test system. Automobile exhaust gas condensate was collected and separated into polycyclic aromatic hydrocarbon (PAH)-containing and PAH-free fractions by liquid-liquid distribution between methanol + water + cyclohexane and cyclohexane + nitromethane, respectively. Carbazol and indole derivatives as well as aromatic amines remained predominantly in the PAH-free methanolic phase. Tests involving topical application to the skin of CFLP mice showed that the N-containing and other water-soluble carcinogens do not contribute significantly to carcinogenicity. The results therefore support the assumption that the carcinogenic effect of automobile exhaust condensate is due to the PAH content. (13 refs)

78-6301 Simultaneous Gas-Chromatographic Profile Analysis of Carcinogenic Polycyclic Aromatic Compounds: Polycyclic Aromatic Hydrocarbons, Carbazoles, Acridines/Aromatic Amines. (Eng) Grimmer, G. (Bismisches Institut für Umweltcarcinogene, Sieker Landstrasse 19, 2070 Ahrensburg, W. Germany); Bohnke, H.; Ujjack, K. W. *Fresenius Z Anal Chem* 290(2): 147; 1978.

termination of the carcinogenic risk of polycyclic aromatic compounds to humans by a simultaneous gas-chromatographic procedure is outlined. (6 refs)

78-6305 Persistent Pesticides and Environmental Chemicals Are Taken Up to a Greater Extent than Non-Persistent Compounds by Cultured Human Cells. (Eng) Murakami, M. (Inst. Physical Chemical Res., Wako-shi, Saitama 351, Japan); Fukami, J. *Bull Environ Contam Toxicol* 19(4): 423-427; 1978.

Data on the cellular uptake of 11 pesticides by cultured human embryonic lung diploid cells are presented. The pesticides dichlorodiphenyltrichloroethane (DDT), dieldrin, aldrin 2,4,5,2',5'-hexachlorobiphenyl (PCB), hexachlorobenzene (HCB), carbaryl, malathion, parathion, chlorodimeform, 2,4,5-trichlorophenoxy-1-acetic acid (2,4,5-T), and 2,4-dichlorophenoxy-1-acetic acid (2,4-D) showed the following uptake levels (expressed as picomoles/mg cell protein) at 48 hr of incubation: 4,830, 4,380, 3,640, 1,740, 778, 945, 180, 22.6, 32.4, 9.9, and 3.7, respectively. Thus, persistent pesticides such as DDT, dieldrin, aldrin, PCB, and HCB were taken up by cells to a greater extent than nonpersistent pesticides. The considerable amount of carbaryl taken up by the cells suggests that the naphthalene ring in the carbaryl molecule may be involved in the incorporation potential of this compound. The effect of the above pesticides on cell growth was also investigated; most compounds were not toxic at the same concentration (4×10^{-6} M) and over the same experimental period as in the uptake experiments. The herbicides 2,4-D and 2,4,5-T, although less incorporated than the insecticidal and industrial chemicals, appeared to be more toxic. It is evident that differences in uptake are not the cause of the different degrees of cytotoxicity of the chemicals. (13 refs)

78-6306 Tumor-promoting Phorbol Esters Inhibit Binding of Epidermal Growth Factor to Cellular Receptors. (Eng) Lee, L. S. (Inst. Cancer Res., Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032); Weinstein, I. B. *Science* 202(4365): 313-315; 1978.

Tumor-promoting phorbol esters and related plant diterpenes were tested for their ability to inhibit the binding of ^{125} I-labeled epidermal growth factor (EGF) to HeLa cells. Extremely low concentrations [0.25-50 nanograms (ng)/ml] of 12-O-tetradecanoylphorbol-13-acetate (TPA) and related compounds produced a dose-dependent decrease in ^{125} I-EGF binding. At 25 ng/ml (4.2×10^{-8} M), TPA inhibited the binding of ^{125} I-EGF by 90%. In decreasing order of effectiveness, the test compounds that inhibited EGF binding were TPA, merzerein, gnilatimacrin, gnidilatin, phorbol-12,13-didecanoate (PDD), and phorbol dibenzoate. Inhibition occurred when the test agent was added 90 min before or simultaneously with EGF. Phorbol, 4 α -phorbol-12,13-didecanoate, 4-O-methyl-12-O-tetradecanoylphorbol-13-acetate, gnidipalmin, and anthralin did not have an appreciable effect on ^{125} I-EGF binding when tested at concentrations up to 100 ng/ml. The inhibitory effect, therefore, occurs at concentrations as low as 10^{-8} - 10^{-9} M and possesses marked structural specificity and stereospecificity. These re-

sults also parallel the structural requirements for promoting activity in the two-stage mouse skin carcinogenesis assay. Inhibition of binding appears to be due to a decrease in the number of available EGF receptors rather than to a change in receptor affinity. These results suggest that certain biologic effects of tumor promoters may result from alterations in the function of cell-surface receptors involved in growth regulation. (48 refs)

- 78-6307 Blocking Tumor Promotion by Protease Inhibitors.** (Eng) Troll, W. (Dept. Environmental Medicine, New York Univ. Medical Center, New York, NY, 10016); Levitz, M. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1245-1250; 1978.

The influence of protease inhibitors on tumor promotion in mouse skin and the association between estrogens and plasminogen activation in mouse uterus were investigated. Treatment of mouse skin with 1 μ g phorbol myristate acetate (PMA) resulted in the appearance of appreciable protease activity (35 fluorescence units/mg protein/hr); this activity was inhibited by tosyllysine chloromethyl ketone, a protease inhibitor. In skin tumor studies, tumor appearance was delayed 50-100 days by the application of protease inhibitors 3x/wk. Tumors initiated on the skin of female mice with 7,12-dimethylbenz(a)anthracene and promoted 2 wk later with croton oil were suppressed by the application of glucocorticoids (dexamethasone, Schering No. 11572, prednisolone, hydrocortisone, and cortisone) at 6 and 30 μ g, 5x/wk. Tissue culture studies indicated that dexamethasone elaborates a protease inhibitor. The association between estrogens and plasminogen activation was investigated by treating ovariectomized young mice with 0.1 μ g estradiol bid for 3 days. This resulted in the appearance of plasminogen activator specifically localized in the 12,000 g pellet, perhaps bound to the plasma membrane, and the nucleus. Inoculation of normal cycling female mice with a mixture of the protease inhibitors Antipain (3.0 mg) and Leupeptin (20 mg) for 15 days caused a significant diminution in uterine wt, total DNA, and total protein. The role of plasminogen activator may be at an early stage of tumor promotion; hormones may act in a similar manner. (12 refs)

- 78-6308 The Nucleotide-Permeable *Escherichia coli* Cell, a Sensitive DNA Repair Indicator for Carcinogens, Mutagens, and Antitumor Agents Binding Covalently to DNA.** (Eng) Thielmann, H. W. (Deutsches Krebsforschungszentrum, Institut für Biochemie, Im Neuenheimer Feld 280, D-6900 Heidelberg, West Germany); Gersbach, H. *Z Krebsforsch* 92(2): 177-214; 1978.

The use of ether-permeabilized (nucleotide-permeable) *Escherichia coli* cells in assay of capability for DNA-binding and stimulation of excision repair of 11 ultimate carcinogens, 10 proximate carcinogens, 2 tumor promoters, 6 mutagens, and 12 antitumor agents was investigated. The strains *uvrA* and *uvrB* used in the study were the wild types, H 540, KMBL 1789, and the mutants *uvrA* (H 512) and *uvrB* (H 551). All the ultimate carcinogens (alkylating, alkylating, arylalkylating agents) and the mutagens such as hydrogen peroxide and acridine derivatives caused DNA excision repair in wild type cells and simultaneously inhibited replication DNA synthesis to various degrees. Proximate carcinogens such as dimethyl nitrosamine and the aflatoxins require activation for DNA-binding did not induce excision repair. Intercalating mutagens such as quinacrine and ethidium bromide inhibited replicative DNA synthesis, however they were not repair inducers. The tumor promoters 12-O-tetradecanoyl-phorbol-13- and phorbol-12,13-didecanoate did not cause excision repair, even when applied in high concentrations, nor did they inhibit excision repair synthesis stimulated by N-methyl-N-nitrosourea or N-acetoxy-2-acetylaminofluorene. The antitumor agents were classified in two groups on the basis of their effect on DNA synthesis: members of the first group known to bind covalently to DNA [bleomycin, N-bis(2-chloroethyl)-N-nitrosourea, etc] stimulated excision repair polymerization and inhibited DNA replication; the other group of antitumor agents, known to react with DNA by noncovalent binding [*cis*-Pt(II) diamine complexes, adriamycin, etc] inhibited DNA replication without stimulating repair synthesis. It is concluded that the ether-permeabilized *E. coli* cell can be successfully used as assay for DNA repair-inducing and replication-inhibiting activity. (110 refs)

- 78-6309 Effect of Tumor Promoters on the Response of Cultured Embryonic Chick Ganglia to Nerve Growth Factor.** (Eng) Ishii, D. N. (Dept. Pharmacology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032). *Cancer Res* 38(11, part 1): 3886-3893; 1978.

The effects of the tumor-promoting agent 12-O-tetradecanoylphorbol-13-acetate (TPA) on nerve growth factor (NGF)-induced neurite outgrowth (NOG) were studied in cultured chick embryonic ganglia. There was no detectable NOG in the absence of NGF, but in its presence [1 nanogram(ng)/ml], a max response was attained in 24 hr and sustained for at least 48 hr. The addition of TPA (100 ng/ml, 1.7×10^{-7} M) to the culture medium inhibited further NOG for 24 hr, after which there was a gradual increase in outgrowth, even in the presence of fresh TPA. Neurites formed in the presence of NGF (10 ng/ml) + TPA (200 ng/ml) were shorter, thicker, and sparser than those of NGF-treated cultures. In cytotoxicity tests, TPA alone substantially enhanced the survival of ganglion cells. TPA + NGF appeared to increase the number of surviving cells over that produced with either agent alone. Thus, TPA is not cytotoxic to ganglion cells at concentrations that antagonize NGF. Other plant di-

enes that are tumor promoters in the mouse skin carcinogenesis system (phorbol-12,13-didecanoate, ingenol dibenzoate, and mezerein) also inhibited the ganglia response to NGF, but structurally related nonpromoting compounds were inactive. The concentration of NGF that induced a 50% max NOG response in sensory ganglia was 0.6×10^{-11} M. The antagonism of NGF by TPA was dose-dependent and noncompetitive. TPA concentrations that extensively inhibited NOG did not affect the amount of ^{125} I-labeled NGF bound to specific sites on dissociated dorsal root ganglion neurons, supporting the theory that TPA acts at a stage beyond the initial interaction of the factor with its receptive site. (51 refs)

6310 Specificity of Response in Hamster Cells Induced to Produce Plasminogen Activator by the Tumor Promoter, 12-O-Tetradecanoylphorbol-13-acetate. (Eng) Christman, J. K. (Dept. Biochemistry, Mount Sinai Medical Center, New York, NY, 10029); Copp, R. P.; Pedriotti, L.; Whalen, C. E. *Cancer Res* 38(11, part 1): 3854-3860; 1978.

The effect of the tumor-promoting agent 12-O-tetradecanoylphorbol-13-acetate (TPA) on the form of plasminogen activator (PA) produced by cells in culture was studied using several hamster cell lines. TPA enhanced PA production only in hamster cells that synthesize a PA that is immunologically identical to that of normal hamster lung cells. No enhancement of PA production was detected in hamster cells (kidneys, ovary, melanoma, or glioma) that synthesize a PA of different antigenic form. Neither the tissue of origin nor the transforming agent served as an absolute determinant of the form of PA produced. Two of three simian virus 40 (SV40)-transformed early-passage Chinese hamster lung cells, a subclone of the DON hamster lung line selected for azaguanine resistance, and one of two SV40-transformed hamster kidney lines produced the lung-type PA. Cells of the third SV40-transformed lung culture produced a PA distinct from that of normal hamster lung cells. In the presence of TPA, however, this line synthesized PA of the lung form. Thus, TPA was able to induce the reexpression of at least one parameter of the original phenotype, synthesis of the lung form of PA. These results suggest that the two antigenically distinct PA's are separate gene products. The relationship, if any, between the ability of TPA to increase PA production and its ability to promote tumor formation in mouse skin is not known. (46 refs)

78-6311 Distribution of 3-Hydroxyanthranilic Acid in Mice. (Eng) Watanabe, M. (Dept. Analytical Chemistry, Faculty Pharmaceutical Sciences, Teikyo Univ., Yagami, Kanagawa-ken 199-01, Japan). *Gann* 69(4): 585-587; 1978.

Male (BALB/c x DBA/2)F₁ mice were inoculated sc with

^{3} H-hydroxyanthranilic acid (^{3} H-HAA: 2 mg, 748 μ Ci) and, 30 and 60 min and 6 hr later, the distribution of ^{3} H was observed by whole-body autoradiography and radioactivity measurements, and metabolites in organs and urine were measured by paper and thin-layer chromatography. At 30 and 60 min after injection, the radioactivity was found mainly in the liver and kidneys; it was distributed almost uniformly in other organs. After 6 hr, the radioactivity remained in the kidneys and lymphoid organs. However, at 30 min and 6 hr after injection, neither HAA nor any carcinogenic metabolites could be detected in the liver, kidneys, spleen, or lymph nodes. Considerable amounts of HAA and its sulfate were found only in urine. These results suggest that HAA is metabolized rapidly and does not accumulate in a specific organ. However, urinary organs may be at risk of tumor development because of the rapid excretion of most of the compound in urine. (8 refs)

78-6312 Studies on the Hepatic Microsomal Metabolism of [^{14} C]Phenanthrene. (Eng) Chaturapit, S. (Dept. Pharmacy, Univ. Sydney, New South Wales 2006, Australia); Holder, G. M. *Biochem Pharmacol* 27(14): 1865-1871; 1978.

The metabolism of ^{14} C-phenanthrene by liver microsomes from Wistar rats, SW and DBA/2J mice, and guinea pigs was examined using untreated, sodium phenobarbital (PB)-pretreated, and 3-methylcholanthrene (3-MC)-pretreated animals. Metabolite profiles were obtained by comparing the thin-layer chromatographs of the reaction products with chromatographs of authentic reference compounds. Trans-Dihydrodihydroxyphenanthrenes were the major metabolites in all preparations. With all reactions except for the one in which microsomes from 3-MC-pretreated guinea pigs were used, trans-9,10-dihydro-9,10-dihydroxyphenanthrene predominated. With microsomes from the 3-MC-pretreated guinea pigs, phenanthrene 1,2-dihydrodiol was the major metabolite. Addition of cyclohexene oxide (5.0 mM) to the incubation mixture inhibited dihydrodiol formation in rat and mouse preparations by 90% and in guinea pig preparations by 70%. Phenols and phenanthrene 9,10-oxide were produced instead. Compared with control microsomes, increases in phenanthrene metabolism occurred with microsomes from all PB-pretreated animals and with microsomes from 3-MC-pretreated rats and SW mice, a pattern similar to that seen for the induction of aryl hydrocarbon hydroxylase. 78-6313 Excision of Hydrocarbon-DNA Adducts and Consequent Cell Survival in Normal and Repair Defective Human Cells. (Eng) McCaw, B. A. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Dipple, A.; Young, S.; Roberts, J. *J. Chem Biol Interact* 22(2/3): 139-151; 1978.

An attempt was made to demonstrate selectivity of excision in normal human fibroblasts, xeroderma pigmentosum (XP) variants that are not deficient in excision repair, and in partially excision-repair-deficient XP fibroblasts. Survival curves for UV-irradiated normal human cells and XP variant cells (XPB4BE) were indistinguishable. In comparison, cells from XP complementation group A (XP12BE) were very sensitive to UV radiation. Complementation group C (XP2BE) cells were almost as sensitive as group A cells. These survival phenomena paralleled the known unscheduled DNA synthesis responses of these cells to UV radiation, which, compared with normal cells, are: XP4BE, 100%; XP2BE, 20%; XP12BE, 2%. The relative capacities of these cells to excise 7-bromomethylbenz(a)anthracene (BMBA)-DNA adducts and to survive treatment with the carcinogen were similar to the responses to UV radiation, except that the XP2BE cell line excised and survived this damage far better than anticipated from its response to UV radiation. Moreover, although the ratio of hydrocarbon-adenine adduct to hydrocarbon-guanine adduct remaining in DNA decreased notably with excision in normal and variant cells, this ratio did not change significantly with excision in XP2BE cells. The relationship between greater excision capacity and increased cell survival in the experiments with BMBA indicates that the unexcised damage is responsible for the cell-killing action of this agent. The different relative repair and survival responses of these cell lines to UV radiation and to BMBA indicate that in at least one of these cell lines (XP2BE), and possibly all the lines, different cellular mechanisms are involved in the repair of DNA damage resulting from UV radiation and that resulting from chemical carcinogen treatment. (22 refs)

78-6314 Cytogenetic Mapping of the Trisomic Segment of Chromosome 15 in Murine T-Cell Leukemia.

(Eng) Wiener, F. (Dept. Tumor Biology, Weizmann Inst. Science, Rehovot, Israel); Ohno, S.; Spira, J.; Haran-Ghera, N.; Klein, G. *Nature* 275(5681): 658-660; 1978.

A chromosome segment located distal to the T6 breakpoint of chromosome 15 was found to be duplicated in 7,12-dimethylbenz(a)anthracene-induced T-cell leukemia in CBAT6T6 mice. These leukemias are associated with trisomy 15, a non-random cytogenetic change also associated with murine T-cell leukemia induced by viruses and x-rays. The induced leukemias were transplanted sc into recipient mice of the opposite sex, and G-banded metaphase plates were prepared from sc tumors, spleens, and bone marrow. Five of six leukemias were aneuploid, with 41 or 42 chromosomes. All the aneuploid leukemias had a trisomy T(14;15)6. The sixth tumor, however, had a banding pattern indistinguishable from that of a normal CBAT6T6 cell. The consistency of the trisomic change emphasizes the specific role of genes associated with chromosome 15 in T-cell leukemia. However, the occurrence of a diploid leukemia in one tumor shows that the change is not exclusive. (9 refs)

78-6315 Chemical Carcinogenesis in C3H/StWi Mice: a Worthwhile Experimental Model for Breast Cancer. (Eng) Smith, G. H. (Lab. Molecular Biology, NIH, Bethesda, MD, 20014); Pauley, R. J.; Socher, S. H.; Meeker, D. *Cancer Res* 38(12): 4504-4509; 1978.

To determine whether the low incidence of mammary tumors in C3H/StWi mice is due to the fact that low-oncogenic mouse mammary tumor virus MMTV(L) is not expressed in these mice, the effects of estrogenic stimulation and 7,12-dimethylbenz(a)anthracene (DMBA) on mammary tumor incidence were examined in C3H/StWi and (BALB/c x C3H/StWi)F₁ mice. None of 18 virgin C3H/StWi females in which 20% diethylstilbestrol (DES) pellets were implanted sc at 5-6 wk of age developed mammary cancer throughout their life-span, which averaged 24.5 mo. Only 2/24 hybrid mice similarly treated developed mammary cancer. In contrast, 17/37 virgin C3H/StWi mice treated with DMBA (50 mg/wk, intragastrically) over a 6-wk period developed mammary tumors at an average of 7.8 mo (range, 4.5-10 mo). Tumors were mainly papillary adenocarcinomas. Mammary dysplasias were found in 73% of the whole-gland mounts examined at 10 mo (3.6 mice). All but three dysplasias were ductal in origin. No hyperplastic alveolar nodules were found. Electron microscopic examination of 14 DMBA-induced mammary tumors failed to reveal the presence of A- or B-type particles, but 11 tumors contained budding or extracellular C-type virions. Evaluation of five tumors for MMTV-specific RNA sequences indicated levels as low or lower than those found in the mammary glands of retired multiparous C3H/StWi females (0.0035%). Much higher levels (0.2%-0.4%) of MMTV-specific RNA to total RNA occurred in MMTV-induced C3H/StWi mammary tumors. Thus, the C3H/StWi subline is different from other C3H sublines in view of its low mammary cancer incidence, low response to estrogenic stimulation, and the fact that it does not produce MMTV(L). It may represent a unique model for the study of viral, chemical, and viral-chemical interactions in the malignant transformation of mammary epithelial cells. (21 refs)

78-6316 A Technique for Localization of Tumours in Hamster Cheek-Pouch Carcinogenesis. (Eng)

MacDonald, D. G. (Dept. Oral Medicine and Pathology, Glasgow Dental Hosp. and Sch., 211 Renfrew St., Glasgow G2 3JZ, Scotland). *Arch Oral Biol* 23(7): 573-577; 1978.

A technique was developed to enable the area of exposure to a carcinogen and of subsequent tumor growth to be predetermined and restricted in the hamster cheek pouch. Thirty male Syrian hamsters received either 0.5% or 0.25% 9,10-dimethyl-1,2-benzanthracene (DMBA) topically, 3x/wk for 6 wk in a restricted (1-cm²) anterior portion of both cheek pouches just posterior to the prominent blood vessels at the pouch mouth. At 15 wk posttreatment, all animals were sacrificed and examined surgically. Tumors were first evident at 5 wk posttreatment, and by time of biopsy at 8 wk, 11 animals had

tors in 13 pouches, but there was no significant difference between the two treatment groups with respect to tumor yield distribution. At sacrifice, 19 animals had developed tumors in 30 pouches, many at multiple sites. In 13 pouches, tumors were within the experimental area; in 9, they were outside this area; and in 8, tumors were within and without defined area. Again, there was no significant difference between the two treatment groups with respect to tumor yield distribution, but the 0.25% group showed significantly higher tumor localization in terms of pouches with tumors inside the experimental area only (8/9 pouches) compared to pouches with tumors outside this area only. This means localization allows sequential studies of carcinogenesis in defined area to be undertaken. (7 refs)

6317 **Azo Dyes Prevent Hydrocarbon-induced Leukemia in the Rat.** (Eng) Huggins, C. B. (Ben May Lab. Cancer Res., Univ. Chicago, Chicago, IL, 60637); La, N.; Russo, A. *Proc Natl Acad Sci USA* 75(9): 44527; 1978.

The azo dyes 1-(p-phenylazophenylazo)-2-naphthol (Sudan III) and 1-(o-tolylazo-o-tolylazo)-2-naphthol (Sudan IV) were investigated as possible protectors against leukemia induced by multiple injections of 7,8,12-trimethylbenz(a)anthracene (7,8,12-TMBA) in Long-Evans rats. Three groups of female rats were given four 35-mg/kg injections of 7,8,12-TMBA, iv, 2-wk intervals. Two groups were fed 1 mg of either dye 24 hr before each iv injection; controls were fed same oil. In rats fed Sudan III, leukemia incidence was 60%, mammary cancer incidence 60%. Analogous figures for rats fed Sudan IV were 21% and 57%. Of control rats, 21% developed leukemia and 43%, mammary cancer. Three groups of male rats received 7,8,12-TMBA as above. Two groups received Sudan III at 48 and 24 hr prior to each injection, one (Group I) at a dose of 1 mg, and the other (Group II) at a dose of 10 mg. The incidence of leukemia in Group I was 6%, that in Group II, 0%. Controls developed leukemia at a rate of 92%. Daily feeding of 1 mg Sudan III to eight female rats for 4 days produced a progressive increase in the hepatic menadione reductase concentration, but the protein concentration was unchanged. A single iv injection of 35 mg/kg 7,8,12-TMBA produced a transient leukopenia, but no changes in WBC counts were seen in similarly treated rats protected with 1 mg Sudan III. All 16 female rats given a single injection of 75 mg/kg 7,12-DMBA expired in 1-3 days. In an identical group protected with 1 mg Sudan III 24 hr before DMBA injection, no rats died, although 50% eventually developed leukemia. Sudan III itself was not found to be carcinogenic. (18 refs)

6318 **Development of Experimental Brain Tumors under Amine Metabolism Modulation.** (Rus) Zumanis, E. A. (Dept. Pharmaceutical Chemistry, Riga

Medical Inst., Riga, USSR); Plaude, O. O.; Buikis, I. M. *Vopr Onkol* 24(9): 71-77; 1978.

9,10-Dimethyl-1,2-benzanthracene (DMBA)-induced brain tumor mortality and its relationship to brain serotonin levels were studied over a 10-mo period in Wistar rats with DMBA implanted into their cerebellum. The development of cerebellar tumors was accompanied by a depletion of the serotonin level in the cerebellum, but the level in the hypothalamus remained unchanged. An inverse correlation was found between DMBA-induced brain tumor mortality and serotonin levels. Topical administration of monoamine oxidase inhibitors before the precancerous stage (before day 120 after DMBA implantation) reduced tumor incidence and tumor mortality by reducing the number of astrocytomas and histogenetically related glioblastomas. The monoamine oxidase inhibitors had no effect on the malignant transformation of other neuroectodermal cells. The findings indicate that serotonin (the levels of which are increased by monoamine oxidase inhibitors) increases the resistance of astrocytes to malignant transformation. (21 refs)

78-6319 **Hemopexin and Aryl Hydrocarbon Hydroxylase Induction in the Mouse and in Cell Culture.**

(Eng) Owens, I. S. (Developmental Pharmacology Branch, Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014); Nebert, D. W.; Liem, H. H.; Muller-Eberhard, U. *Biochem Pharmacol* 27(12): 1665-1669; 1978.

Hemopexin (HP) and aryl hydrocarbon hydroxylase (AHH) induction among inbred mouse strains and among offspring derived from appropriate genetic crosses was examined along with HP and AHH levels in several rat hepatoma-derived cell culture lines to determine whether an association exists between HP induction and the Ah allele. Treatment of three responsive mouse strains, C57BL/6N (B6), Balb/cAnN, and C3H/HeN, with a single dose (80 mg/kg, ip) of 3-methylcholanthrene (3-MC) or β -naphthoflavone (NF) increased plasma HP levels 71%-160%. The nonresponsive strains DBA/2N, NZB/BLN, and NZW/BLN had increases of 14% to 60%. In B6 mice, the greatest rise in HP levels occurred between 24 and 48 hr. AHH activity induced by 3-MC occurred during the first 24 hr. The increase in HP therefore appears to be subsequent to AHH induction by 3-MC. Administration to the mice of 0.05% phenobarbital in drinking water for up to 14 days induced similar levels of AHH activity in both responsive and nonresponsive mice. Again, the increase in HP followed AHH induction. AHH was not inducible in 6/18 3-MC treated (B6 x NZW)_{F2} offspring. In hepatoma cell lines grown in culture and treated with 13 μ M benz(a)anthracene (BA), HP production occurred in H-4-II-E but not in HTC or Hepa-1 cells, but a relationship between inducible AHH activity and plasma HP levels could not be inferred. HP appearance was equivalent in BA-treated and control H-4-II-E cultures, whereas AHH induction occurred primarily in the BA-treated cultures. Frequent remov-

al of tissue culture medium resulted in an increased secretion of intracellular HP to the surrounding medium. The reason for this effect is not known. (33 refs)

- 78-6320 The Topology of Epoxide Hydratase and Benzopyrene Monooxygenase in the Endoplasmic Reticulum of Rat Liver.** (Eng) Seidegard, J. (Arrhenius Lab., Dept. Biochemistry, Univ. Stockholm, Fack, S-106 91 Stockholm, Sweden); Moron, M. S.; Eriksson, L. C.; DePierre, J. W. *Biochim Biophys Acta* 543(1): 29-40; 1978.

The distribution of benzo(a)pyrene monooxygenase and epoxide hydratase, in the liver microsome subfractions of control and of phenobarbital (PB)- and methylcholanthrene(MC)-treated rats was investigated. Male Sprague-Dawley rats were injected ip with 20 mg/kg MC on days 5, 3, and 1 before sacrifice or with 80 mg/kg PB on days 5-1 before sacrifice. The specific activities of these enzymes in the rough and smooth microsomes from control and PB-treated rats were approx equal. After treatment with MC, however, the activity of benzo(a)pyrene monooxygenase was four times higher and that of epoxide hydratase two times higher in the rough vesicles. Differential centrifugation revealed that both enzymes were dispersed uniformly throughout the microsomal vesicles. It is concluded that these two enzyme systems may form a complex of unique stoichiometry in the microsomal membranes from control rats, not in those from MC-treated rats. Studies with proteases and diazobenzene sulfonate suggest that epoxide hydratase is located deep within the lipid phase of the membrane of the hepatic endoplasmic reticulum. (31 refs)

- 78-6321 An Experimental Approach to the Breast Cancer, Reserpine Problem.** (Eng) Homburger, F. (Bio-Res. Inst., 9 Commercial Ave., Cambridge, MA, 02141); Van Dongen, C. G.; Adams, R. A.; Soto, E. A.; Pai, K. J. *Cancer Lett* 4(3): 177-183; 1978.

The effect of reserpine on methylcholanthrene (MC)-induced breast cancer was studied in BIO 15.16 Syrian hamsters, a strain previously shown to be sensitive to the induction of mammary cancer by MC. There were seven experimental groups. Group 0 (25 hamsters) received 10 µg reserpine ip three times weekly for life. (An initial dose of 100 µg was reduced after 1 wk because of intolerance.) Group I (25) received 50 gastric gavages of 0.05 mg MC. Group II received (25) reserpine + MC. Group III received reserpine + 50 gavages of 0.1 mg MC. Group IV received 50 gastric gavages of 4 mg MC. Group V received the vehicle for reserpine and MC. Group VI received no treatment. All MC doses except the 4-mg dose were non-carcinogenic. The survival curves of all groups except Group IV were not significantly different from each other. Mammary tumors were noted only in 11 Group IV animals; other Group IV tumors included 3 adenocarcinomas of the colon and cecum, 2 lymphomas, and 2 sar-

comas. Multiple mammary tumors were a frequent finding. Metastasis of mammary gland carcinoma to the cervical, axillary, and/or inguinal lymph nodes was observed in 10 animals, metastases to the lungs in 2. No tumors were noted in Groups 0 and I. Group II had 1 sarcoma, Group III 2 lymphomas, Group V 1 sarcoma, and Group VI 1 lymphoma. The results do not conclusively rule out or demonstrate cocarcinogenicity of reserpine. (9 refs)

- 78-6322 Metabolic and Enzymatic Factors in Tumor Susceptibility.** (Eng) Kellermann, G. H. (Div. Human Oncology, Univ. Wisconsin Medical Sch., Madison, WI). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for Detection and Prevention of Cancer in New York, April 1-5, May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY) : Vol. 2 (Part I), 2404 pp.; 1517-1524; 1978.

The relationship between aryl hydrocarbon hydroxylase (AHH) activity and susceptibility to carcinogenic polycyclic aromatic hydrocarbons (PAH) was studied. Human lymphocytes were cultured for 2 days in the presence of 2 mg/ml phytohemagglutinin and pokeweed prior to the administration of 3-methylcholanthrene or benzo(a)anthracene to induce AHH activity. Individual inducibility was expressed as the ratio of AHH activity in the PAH-treated cultures to AHH activity in the cultures without treatment. The lymphocytes were obtained from 289 normal subjects, patients with bronchogenic carcinoma (50) or laryngeal carcinoma (37), and 46 patients (cancer control group) with Hodgkin's disease or cancers of the skin, gastrointestinal tract, head and neck, breast, uterus, prostate or bladder. Previous family and population studies have revealed considerable interindividual variation of this enzyme complex and demonstrated its genetic control. Ninety percent of the healthy subjects had low or intermediate AHH inducibilities in their lymphocytes. However, 96% of the lung cancer patients, all heavy smokers, had intermediate (66.0%) or high (30.0%) AHH inducibility. This distribution pattern was not seen in the laryngeal cancer patients (19.0% with high inducibility) or in the cancer control group (10.9% with higher inducibility). It is suggested that cigarette smokers with high AHH inducibility have a higher risk of developing lung cancer than persons with low inducibility. Ninety percent of the 289 healthy subjects had low (114) or intermediate (118) AHH inducibilities in their lymphocytes. (18 refs)

- 78-6323 1,2-Dihydro-1,2-dihydroxy-5-methylchrysene, A Major Activated Metabolite of the Environmental Carcinogen 5-Methylchrysene.** (Eng) Hecht, S. (Div. Environmental Carcinogenesis, Naylor Dana Inst. Disease Prevention, American Health Foundation, Valhalla, NY)

, 10595); LaVoie, E.; Mazzaresse, R.; Amin, S.; Bedenko, Hoffmann, D. *Cancer Res* 38(7): 2191-2194; 1978.

the metabolic activation of the environmental carcinogen methylchrysene was studied by combining high-pressure liquid chromatographic analysis of metabolites formed in vivo with assays of these metabolites for mutagenic activity toward *Salmonella typhimurium*. Metabolites were formed during the incubation of 5-methylchrysene with the 9000 x g supernatant from Aroclor-treated rat livers. With the use of reverse-phase columns, the metabolites were resolved into several peaks. Significant mutagenic activity was observed primarily in one peak and to a lesser extent in a second peak. The major mutagenic metabolite was identified as 1,2-dihydro-1,2-dihydroxy-5-methylchrysene (7.0% from 5-methylchrysene), and the secondary mutagenic metabolite was identified as 7,8-dihydro-7,8-dihydroxy-5-methylchrysene (2.6% from 5-methylchrysene). The results indicate that 1,2-dihydro-1,2-dihydroxy-5-methylchrysene is a proximate mutagenic metabolite of methylchrysene and support the hypothesis that carcinogenic polynuclear aromatic hydrocarbons can be activated through the formation of specific angular ring diol-epoxides. (no refs)

6324 Relationship Between DNA Damage, Cell Survival and DNA Repair in CHO Cells after In Vivo Metabolic Activation of Promutagens (Meeting Abstract). (Eng) Douglas, G. R. (Environmental Mutagenesis Section, Dept. Natl. Health and Welfare, Tunney's Pasture, Ottawa, Canada); Grant, C. E. *Can J Genet Cytol* 20(3): 442; 1978. (no refs)

6325 Carcinogen-induced DNA Repair in Nucleotide-Permeable *Escherichia coli* Cells. Analysis of DNA Repair Induced by Carcinogenic K-Region Epoxides 1,2,3,4-Diepoxybutane. (Eng) Thielmann, H. W. (Deutsches Krebsforschungszentrum, Institut für Biochemie, Im Neuenheimer Feld 280, D-6900 Heidelberg, West Germany); Thielmann, H. *Z Krebsforsch* 92(2): 157-176; 1978.

Enzymic activities catalyzing DNA repair in ether-permeabilized (nucleotide-permeable) *Escherichia coli* cells exposed to carcinogenic K-region epoxides or the aliphatic epoxide 1,2,3,4-diepoxybutane (DPB) were identified by determination of repair polymerization and size reduction of damaged DNA. The requirement for the *uvr* gene function in excision repair was tested using wild type and *uvr* A and *uvr* B mutant *E. coli* cells. When exposed to the carcinogenic K-region epoxides 7-methyl- and 7,12-dimethylbenz(a)anthracene-5,6-oxide, chrysene-5,6-oxide, and benzo(a)pyrene-4,5-oxide, the wild type cells (KMBL 1788; H 540) exhibited DNA excision repair, but the *uvr* A and *uvr* B cells did not. The K-region epoxide phenanthrene-9,10-oxide was effective in all *E. coli* strains tested. DPB and the 6,7-epoxides of the tumor promotor, 12-O-tetradecanoyl-phor-

bol-13-acetate, elicited DNA repair in the *uvr* A and *uvr* B mutant cells. None of the epoxides induced repair polymerization in a mutant that lacked the 5'-3' exonucleolytic activity of DNA polymerase I (exonuclease VI). Greatly reduced levels of repair polymerization were observed in mutants that lacked DNA polymerase I. It is concluded that excision of K-region epoxide damaged nucleotides is controlled, at least in part, by three repair enzyme activities: a UV-endonuclease (missing in the *uvr* mutants), the 5'-3' exonucleolytic activity of DNA polymerase I, and an intact DNA polymerase. Excision of DPB damaged nucleotides requires in addition a *uvr*-independent repair endonuclease, which is probably endonuclease II, DNA glycosidase(s), and/or apurinic endonuclease(s). (58 refs)

78-6327 Benzo(a)pyrene Absorption from the Intestinal Tract of the Rat with Emphasis on Lymphatic Uptake and Tissue Distribution. (Eng) Reid, J. B. (Univ. Cincinnati, Cincinnati, OH). *Diss Abstr Int B* 39(5): 2205; 1978. (no refs)

78-6328 Antimutagenic Effects of 2(3)-tert-Butyl-4-hydroxyanisole and of Antimicrobial Agents. (Eng) Batzinger, R. P. (Dept. Pathobiology, John Hopkins Medical Inst., Baltimore, MD, 21205); Ou, S. Y.; Bueding, E. *Cancer Res* 38(12): 4478-4485; 1978.

To determine antimutagenic effects of the antioxidants 2(3)-tert-butyl-4-hydroxyanisole (BHA) and ethoxyquin (EQ), diets containing 0.75% BHA or 0.5% EQ were fed to female CD-1 mice that were subsequently treated with benzo(a)pyrene (BP: 100 mg/kg im in sesame oil), hycanthone (60 mg/kg im as the aqueous soln of methane sulfonate salt), and metronidazole, diazepam, or mebendazole (each 200 mg/kg by gastric intubation). BHA and EQ markedly decreased the level of mutagens present in BP-treated mice, as determined by a host-mediated assay and tests with *Salmonella typhimurium* strains TA100 and TA98. BHA also reduced the mutagenic activities in vivo of the four antischistosomal compounds. These effects were accompanied by increases in the thiol levels of some tissues. The production of mutagenic metabolites of two other antischistosomal drugs, 4-isothiocyano-4'-nitrodiphenylamine and oxamniquine, was not reduced by BHA treatment. However, reductions in mutagenicity were achieved by the administration of enteric antibacterial agents, which implicates intestinal microorgan-

isms in the mutagenic activation of certain chemical agents. Combined treatment of mice with BHA and enteric antimicrobial agents reduced the levels of mutagens derived from metronidazole by more than 90%, and the combined treatments were more effective than was either treatment alone. (37 refs)

- 78-6329 Selective Fluorescence Quenching of Benzo(a)-pyrene and a Mutagenic Diol Epoxide Derivative in Mouse Cells.** (Eng) Wade, C. G. (Dept. Chemistry, Univ. Texas at Austin, Austin, TX, 78712); Baker, D. E.; Bartholomew, J. C. *Biochemistry* 17(20): 4332-4337; 1978.

Fluorescence and flow cytometric studies were made of the effects of various quenchers on suspensions of cultured mouse cells containing benzo(a)pyrene (BP) and its diol epoxide (DE) 7 β , 8 α -dihydroxy-9 α , 10 α -epoxy-7,8,9,10-tetrahydrobenzo(a)pyrene. The overlap of the fluorescence spectra of BP and its metabolites, particularly the DE, had previously prevented the use of fluorescence in investigations of the impact of these carcinogens on cell populations. The cells used were NMuLi (mouse liver epithelial cells), BALB A31 3T3 HYF (mouse fibroblast cells), and MSV/MLV BALB 3T3 A31 HYF (Moloney sarcoma virus-transformed mouse fibroblast cells). The most effective quencher was the lipid-soluble N-octyl iodide, which quenched the BP emission by a factor of 6 with little change in the DE emission. At comparable molarity, methylene iodide was a relatively effective quencher for both aromatic hydrocarbons, but it was not selective. The ionic quencher KI was ineffective. The results were, in general, independent of the type of mouse cell strain. Information on the location of the hydrocarbons in the cells is given. The selectivity of n-octyl iodide may be due to the fact that collisions with BP are much more likely than collisions with the DE. Thus, the possible locations of the DE are: bound in proteins or attached near the polar head groups of lipids in membranes or attached in a nonlipid portion of the cell. The selective quenching technique should have broad application to fluorometric studies of various kinds in biological systems, including flow cytometry and cell sorting. (44 refs)

- 78-6330 Health Aspects of Water Chlorination with Special Consideration of the Cocarcinogenicity of Chlorine. II. The Cocarcinogenicity of Chlorine.** (Ger) Pfeiffer, E. H. (Hygiene-Institut, Hochhaus am Augustusplatz, D-6500 Mainz, W. Germany). *Zentralbl Bakteriol [Orig B]* 166(2/3): 185-211; 1978.

The possible cocarcinogenicity of chlorine and polycyclic aromatic hydrocarbons was investigated. A 0.22% or 0.44% acetic benzo(a)pyrene (BP) soln was applied twice weekly to the depilated skin of the backs of female NMRI mice for 10 wk to a total dose of 750 or 1,500 μ g/animal. In addition, various groups were treated with a 1% NaOCl soln either

before, during, or after the BP treatment. After 128 wk tumor development was considerably slowed or terminated prematurely in the groups given a chlorine pretreatment of 750 or 1,500 μ g BP and in the groups that had received chlorine after applications of the lower BP dose. Tumor growth in the remaining groups was not affected. Administration of chlorine before BP noticeably reduced the number of tumors considerably; only a very slight reduction was found in the remaining test groups. Chlorine treatment decreased the number of carcinomas among the tumors by about 40%, regardless of the treatment method or the dosage. The mean tumor induction times were not significantly affected by chlorine treatment, and there were no major differences in mortality rates among the groups. Possible mechanisms of action of chlorine are discussed. (162 refs)

- 78-6331 Pulmonary Metabolism of Epoxides.** (C) Smith, B. R. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Maguiness, H.; Ball, L. M.; Bend, J. R. *Fed Proc* 37(11): 2480-2484; 1978.

Epoxide hydrase (EH) and glutathione S-transferase (GST) activities were measured in pulmonary tissue of guinea pigs, rabbits, and rats. On the basis of total organ activity per milligram of protein, pulmonary tissue had a greater capacity to metabolize epoxides than liver tissue. Pulmonary EH and GST were refractory toward inducers such as dieldrin, zanthracene, pregnenolone-16 α -carbonitrile, 2,3,6,7-tetrachlorodibenzo-p-dioxin, and phenobarbital. In the isolated perfused rabbit lung, benzo(a)pyrene 4,5-oxide (BPO) was metabolized by EH and GST at similar initial rates, but EH activity was lost after 5 min at a dose of 1 micromole (μ M) BPO/lung and after 15 min at 5 μ M BPO/lung. Administration of a second dose of BPO (2.5 μ M) 19 min after the first temporarily restored the initial rate of dihydrodiol formation, indicating that the EH system itself was still functional. EH activity is probably lost because of inadequate substrate levels. GST from rabbit lung cytosol separated chromatographically into six peaks containing 1-chloro-2,4-dinitrobenzene (DNCB)-conjugating activity. All six peaks also displayed GST activity toward BPO, but two toward styrene oxide. GST isolated from rabbit lung supernatant fraction was also separated into six peaks, four of which conjugated glutathione with DNCB and BPO, only one of which conjugated glutathione with styrene oxide. The liver protein and total transferase activity levels were higher than those in the lung. Each of the cell types in the lungs is postulated to possess its own specific enzyme level. For the detoxification defense mechanism to be effective, each cell would have to be capable of metabolizing its internally generated epoxides. (25 refs)

- 78-6332 Nephrogenic Hypertension and Carcinogenesis.** (Rus) Litvitskii, P. F. (Dept. Pathologic Physiology,

gy, I. M. Sechenov First Moscow Medical Inst., Moscow, (SR); Kogan, A. Kh. *Vopr Onkol* 24(9): 56-60; 1978.

study was made of the effect of nephrogenic hypertension (NHT), induced by left nephrectomy and stenosis of the artery of the contralateral kidney, on the growth of benzo(a)pyrene (BP)-induced tumors and of transplanted carcinoma RS-1, Walker's carcinoma 45, Walker's carcinosarcoma, Zajdela ascites hepatoma, and Walker's metastasizing carcinosarcoma in outbred male rats. BP was injected sc, the solid tumors were transplanted sc, and Zajdela hepatoma ascites cells were injected into the abdominal cavity. Another group of rats without NHT was treated in the same manner. NHT reduced the latent period of BP-induced tumors by 21.1 days ($p < 0.001$), but it had no effect on the latent period of the transplanted tumors. In addition, NHT increased the absolute wt of all tumors from 33 to 41.4 g, the tumor/body wt ratio from 10.14 to 14.1 ($p < 0.001$), and the frequency of metastases of Zajdela ascites hepatoma and Walker's metastasizing carcinosarcoma. The findings indicate that NHT is a predisposing factor for carcinogenesis, probably as a result of the changes in immunological reactivity and the deficient blood supply and tissue oxygenation that occur during certain phases of hypertension. (14 refs)

78-6333 Elevation of Hepatic Glutathione S-Transferase Activities and Protection Against Mutagenic Metabolites of Benzo(a)pyrene by Dietary Antioxidants. (Eng) Benson, A. M. (Dept. Pharmacology, Johns Hopkins Univ. Sch. Medicine, Baltimore, MD, 21205); Batzinger, R. C.; Ou, S. Y.; Bueding, E.; Cha, Y. N.; Talalay, P. *Cancer Res* 38(12): 4486-4495; 1978.

The effects of the antioxidants 2(3)-tert-butyl-4-hydroxyanisole (BHA) and ethoxyquin (EQ) on the mutagenic metabolites of benzo(a)pyrene (BP) were studied in female C57BL/6J mice and male Sprague-Dawley rats injected im with 10 mg/kg BP. The mice were maintained for 12 days on diets containing 0.75% BHA or 0.5% EQ; alternatively, some mice received BHA (100 to 1,000 mg/kg/day for 4 days) by gavage. The rats were fed a diet containing 0.75% BHA for 8 days. The mutagenic activity of BP urinary metabolites for *Salmonella typhimurium* strains TA98 and TA100 was markedly reduced in the presence of glutathione together with the liver cytosols of animals fed BHA. The liver cytosols of mice and rats maintained on control diets were much less effective in this respect. Dietary BHA increased mouse and rat hepatic glutathione S-transferase (GST) specific activities with 1,2-dichloro-4-nitrobenzene, 1-chloro-4-nitrobenzene, p-nitrobenzylchloride, and δ^5 -androsterone-3,17-dione. The increases were larger (5- to 10-fold) in mice, and they depended on the dose and duration of BHA administration. Increases in GST specific activities were also observed in mouse hepatic cytosols after feeding of EQ. Direct addition of reduced glutathione and purified GST's A and B obtained from rat liver to the mutagenicity assay system mimicked the effect of the rodent cytosols. The

protective effects of the two antioxidants against potent carcinogens may be due, at least in part, to their ability to elevate GST's. These enzymes inactivate arene oxides and other hydrophobic electrophiles by catalyzing their conjugation with glutathione. (45 refs)

78-6334 Carcinogens and Dicumarol: Opposite Effects on Rat Liver NAD(P)H Dehydrogenation. (Eng) Schor, N. A. (Dept. Pathology, Tulane Univ. Sch. Medicine, New Orleans, LA, 70112); Boh, E.; Burke, V. T. *Enzyme* 23(4): 217-224; 1978.

The effects of four carcinogens and dicumarol (DC) on hepatic D-T-diaphorase activity were studied in several groups of Sprague-Dawley rats. Groups 1-4 received benzo(a)pyrene (BP), 7,12-dimethylbenz(a)anthracene, N-acetylaminofluorene, or DC (4.0, 3.9, 4.5, and 3.0×10^{-4} moles/kg, respectively, intragastrically) 24 hr or (DC) 24 and 48 hr before sacrifice. In Group 5, BP was administered for 6 days, DC was given on days 5 and 6, and rats were killed on day 7; in Group 6, 3-methylcholanthrene (3-MC: 7.5×10^{-5} moles/kg, ip) was given for 3 days, DC was given on day 3, and rats were killed on day 5. All carcinogens increased D-T-diaphorase activity 24 hr after administration. DC inhibited this activity, but not the aryl hydrocarbon hydroxylase activity induced by BP and 3-MC. DC potentiated the toxic effects of 3-MC and BP. None of the chemicals affected NADPH cytochrome c reductase activity. It is suggested that carcinogens stimulate two enzyme systems: the microsomal oxidases, which transform some chemicals into highly reactive and toxic compounds, and the cytosolic reductases, which may further detoxify the compounds formed in the microsomal fraction by transforming them into dihydrodiols and phenols. Apparently, there is a competition between both systems. The increase in toxicity with DC (which inhibits the cytosolic system) + BP or 3-MC is presumed due to a lack of detoxification of the two carcinogens. (19 refs)

78-6335 Effect of Anesthetic Agent on Lung Tumor Induction in Hamsters Given Benzo(a)pyrene-Ferric Oxide. (Eng) Henry, M. C. (Environmental Protection Res. Div., US Army Medical Bioengineering Res. and Development Lab., Ft. Detrick, MD, 21501); Port, C. D. *J Natl Cancer Inst* 61(5): 1221-1227; 1978.

Comparison was made of the effects of Brevital, ether, and methoxyflurane (MF) on lung tumor induction in noninbred Syrian golden hamsters given 10 weekly intratracheal instillations of a benzo(a)pyrene (BP)-ferric oxide mixture. Inhalation anesthesia with ether or MF was accomplished by a closed recirculatory system that allowed a short induction time and good control over the concentration of anesthetic. A third group was subjected to systemic induction with 0.4-0.8 ml of 1% Brevital soln ip. Survival rates during the 10 weekly instillations were least for the Brevital-treated

group and greatest for the MF-treated animals. Body wt gain was lower in the ether- and Brevital-treated groups than in the MF-anesthetized group. Animals anesthetized with Brevital had the shortest tumor latency, but tumor incidence was similar in this group and the group treated with ether. Exposure to MF and carcinogen produced a slow onset of deaths from tumors and a lower tumor incidence. The predominant tumor type in all segments of the respiratory tract was squamous cell carcinoma. The most common tumor sites were the trachea and bronchus. Thus, experimental conditions for the induction of lung carcinomas must be standardized if consistent and reproducible results are to be obtained. Inhalation anesthesia with ether does not appear to be the method of choice because of its irritant properties and possible effect on tumor formation. (14 refs)

- 78-6336 Human Skin Aryl Hydrocarbon Hydroxylase: Induction by Coal Tar.** (Eng) Bickers, D. R. (Div. Dermatology, Case Western Reserve Univ., Sch. Medicine, Cleveland, OH, 44106); Kappas, A. *J Clin Invest* 62(5): 1061-1068; 1978.

The effect of cutaneous application of a coal tar (CT) soln (crude CT diluted to 20% with ethanol and polysorbate 80) on aryl hydrocarbon hydroxylase (AHH) activity was investigated in six patients with generalized psoriasis and three with severe atopic dermatitis. CT soln (100 μ l) was applied to the skin, and the site was biopsied 24 hr later. Cutaneous AHH activity was increased two- to fivefold in treated vs untreated skin. AHH activity was also induced in human skin samples incubated with CT for 24 hr, but not to as high a level. In human skin incubated with CT in vitro, there was an initial lag phase of 8 hr followed by a 16-hr period of linearly increasing AHH activity, after which the activity diminished. Max responses both in vivo and in vitro occurred after 24 hr, and enzyme activity in vitro was time-, tissue- and substrate concentration-dependent. The application of a CT soln to neonatal rat skin resulted in a > 10-fold induction of skin AHH activity 24 hr later. Hepatic AHH activity was also markedly increased, indicating that substantial percutaneous absorption had occurred. Assay of several defined constituents of CT for AHH induction showed that benzo(a)pyrene was the most potent inducer of AHH tested followed by pyrene and anthracene. These studies indicate that topical application of CT soln in doses used to treat dermatologic disease causes induction of AHH in human skin, and they suggest that this induced enzyme activity could relate to carcinogenic responses to this agent in skin and other tissues. (44 refs)

- 78-6337 The Identification of High Molecular Weight Polynuclear Aromatic Hydrocarbons in a Biologically Active Fraction of Cigarette Smoke Condensate.** (Eng) Snook, M. E. (Tobacco Lab., Agricultural Res. Service, U.S. Dept. Agriculture, P.O. Box 5677, Athens, GA, 30604);

Severson, R. F.; Arrendale, R. F.; Higman, H. C.; Chort O. T. *Beitr Tabakforsch* 9(2): 79-101; 1977.

As a result of several gas chromatographic procedures including gel filtration and high-pressure liquid chromatography, and of mass spectral, UV absorption, and chromatographic retention data, > 200 compounds were isolated and identified in the most biologically active fraction of cigarette smoke condensate. Newly identified were 3,4-dimethylenene, 3,4-trimethylenepyrene, cyclopenta(c,d)pyrene, 4,5-triethylenetriphenylene, benzo(b)perylene, and several dibenzofluoranthenes. (21 refs)

- 78-6338 Plasminogen Activator in Chick Fibroblasts: Induction of Synthesis by Retinoic Acid; Synergism with Viral Transformation and Phorbol Ester.** (E) Wilson, E. L. (Dept. Clinical Science and Immunology, Medical Sch., Univ. Cape Town, Cape Town, South Africa); Reich, E. *Cell* 15(2): 385-392; 1978.

The effects of vitamin A and its derivatives, the retinoids, on plasminogen activator (PA) synthesis were investigated in chick embryo fibroblast (CEF) cultures. Low concentrations of retinoic acid (RA: 10^{-6} - 10^{-10} M) and the retinoids stimulated PA synthesis by up to 9- or 10-fold, a level somewhat lower than that obtained with optimal concentrations of the potent tumor promoter phorbol myristate acetate (PMA). The effect of RA required protein and messenger RNA synthesis, in contrast to enzyme induction by PMA and/or sarcoma virus transformation, retinoid effects were not significantly inhibited by elevated concentrations of cyclic AMP. The effects of RA and sarcoma virus transformation were synergistic rather than additive in inducing and/or stimulating PA production. Analogous synergism was observed between RA and PMA, but only at suboptimal concentrations of the latter. RA had no effect on PA production in normal or transformed cultures maximally stimulated by PMA. These findings may help to elucidate the role of retinoids in promoting tumor growth, tissue remodeling, and teratogenesis. (27 refs)

- 78-6339 The Induction of Differentiation in Teratocarcinoma Stem Cells by Retinoic Acid.** (E) Strickland, S. (Rockefeller Univ., New York, NY, 10021); Mahdavi, V. *Cell* 15(2): 393-403; 1978.

Plasminogen activator (PA) was used as a marker to study the effects of a number of compounds, especially retinoids, on F9 cells, a teratocarcinoma cell line that undergoes very limited differentiation under normal culture conditions. Retinoic acid at concentrations as low as 10^{-9} M induced multiple phenotypic changes in the cultures. The molecule was increasingly effective as the concentration was raised to 10^{-6} (10^{-7} M was used in most of the experiments); above this amount, it was toxic. Retinoic acid increased PA secretion more than 10-fold in 3 days of culture. There was a concomitant

change in cellular morphology, which closely resembled presumptive endoderm derived from teratocarcinoma yolk bodies. Treatment with retinoic acid alone or in combination with dibutyryl cyclic AMP (10^{-3} M) resulted in increase in intracellular PA levels that paralleled the end secretion of this enzyme, indicating that these compounds do not simply increase secretion of preformed PA but also stimulate the production of active enzyme. The percentage of colonies secreting PA was increased from < 10% to almost 100% by retinoic acid. When cultures were treated first with retinoic acid, washed well, and then treated with dibutyryl cyclic AMP, the cells secreted much more PA than if they were incubated with retinoic acid followed by control medium. Retinoic acid also increased the synthesis of collagenlike proteins and increased the alkaline phosphatase content of the cultures by 20-fold. The nature of these changes, as well as their independence of the continued presence of retinoic acid, are consistent with the proposition that retinoic acid induces differentiation of embryonal carcinoma cells into endoderm. 78-6340 The Effects of Organic Compounds on Mutagen- and Carcinogen-Activating Enzymes In Vivo (Meeting Abstract). (Eng) Bradshaw, J. J. (Dept. Physiology and Medical Biochemistry, Univ. Cape Town Medical School, Cape Town, South Africa); Ivanetich, K. M. *Mutat Res* 154: 154; 1978. (no refs)

78-6341 Fecal Hydroxysteroid Dehydrogenase Activities in Vegetarian Seventh-Day Adventists, Controls, and Bowel Cancer Patients. (Eng) Macdonald, J. (Dept. Medicine, Dalhousie Univ., Halifax, Nova Scotia, Canada); Webb, G. R.; Mahony, D. E. *Am J Clin Oncol* 31(10): S233-S238; 1978.

Free extracts of anaerobic bacteria from the fecal preparations of 14 vegetarian Seventh-Day Adventists (SDA), 8 patients with cancer of the large bowel, and 16 controls were assayed for NAD- and NADP-dependent 3α -, 7α -, and 12α -hydroxysteroid dehydrogenase (HSDA) activities using androsterone and various bile salts as substrates in eight substrate-cofactor combinations. NADP-dependent 12α -HSDH activity was highest in the SDA, while 7α -HSDH content was significantly increased in cancer patients over controls and also over SDA. Fecal pH values for SDA, controls, and cancer patients were 6.46 ± 0.58 , 6.66 ± 0.62 , and 7.03 ± 0.15 , respectively. The cancer pH was significantly higher than the SDA value; and when plotted against values for 7α -HSDH, fecal pH segregated 7/8 cancer patients from the other groups. Parameters for NADP-dependent 3α -HSDH activities using either type substrate were correlated, and the relationship ($r = 0.72$) suggested that this enzyme can oxidize both bile salts and neutral sterols in fecal anaerobic bacteria. Although 7α -HSDH is elevated in bowel cancer pa-

tients, it is presently unclear whether this enzyme is merely a marker, or plays some carcinogenic role itself. (30 refs)

78-6342 Rat Differences in Mammary Tumor Induction with Estrogen and Neutron Radiation. (Eng) Shellabarger, C. J. (Medical Dept., Brookhaven Natl. Lab., Upton, NY, 11973); Stone, J. P.; Holtzman, S. *J Natl Cancer Inst* 61(6): 1505-1508; 1978.

The effects of diethylstilbestrol (DES) and/or neutron radiation on mammary tumor formation were studied in female ACI and Sprague-Dawley (SD) rats. Young adult rats were given sc implants of pellets containing 5 mg DES and 15 mg cholesterol 2 days before irradiation with 0.4, 1.3, or 4.0 rads of 0.43 million electron-volt neutrons. Other rats received DES or irradiation only or no treatment; all rats were studied until death or for a max of 48 wk. DES treatment alone significantly increased the number of ACI rats (52%) with mammary adenocarcinomas (MAC) and the number of MAC/rat (2.74), but it had no effect on the SD rats. Conversely, irradiation only at 4 rads had no effect on the ACI rats, but it significantly increased the number of SD rats (32%) with mammary fibroadenomas (FAC), the number of MAF/rat, and the number of MAC/rat. Combining DES and irradiation 4 rads increased MAC incidence in ACI rats (91%), the incidence of multiple MAC (≥ 16 tumors) (65%), and the number of MAC/rat (15.10) to a total larger than the sum of the effects of the individual agents. Combined treatment in SD rats decreased MFA incidence (3%) and the number of MFA/rat (0.03) to values lower than irradiation alone. Additionally, DES treatment produced large pituitary tumors in 78%-100% of ACI rats and pyometritis in 53% of SD rats. Thus, DES and neutron irradiation acted synergistically on MAC formation in ACI rats but not in SD rats. (15 refs)

78-6343 Perphenazine and Testosterone Metabolism by Mammary Tumours in Oophorectomized Rats. (Eng) Buchan, P. (Dept. Clinical Surgery, Medical Sch., Univ. Edinburgh, Edinburgh EH8 9AG, Scotland); Miller, W. R. *Biochem Soc Trans* 6(1): 135-136; 1978.

The effects of prolactin and ovarian hormones on tumor growth and steroid metabolism were studied in female Sprague-Dawley rats with 7,12-dimethylbenzanthracene-induced (30 mg intragastrically) mammary tumors. When the tumors reached a size of > 2 cm $\times$ 2 cm, the animals were oophorectomized and placed in one of two groups. The treatment group received daily sc injections of 5 mg/kg perphenazine, and the control group received the vehicle only; all animals were killed 14 days later. Oophorectomy alone produced an immediate regression of all tumors, but the combined treatment resulted in a variable response: certain tumors increased in size while others regressed, usually after a short period of growth. Animals from the treatment group showed a signifi-

cantly higher metabolism of testosterone than controls. However, the major metabolites of testosterone in groups were 5α -dihydrotestosterone and 5α -androstenediol. Thus, in oophorectomized animals, perphenazine does not produce the stimulatory effects on mammary tumor growth and steroid metabolism that it has been shown to do in endocrine-intact animals. (3 refs)

- 78-6344 Attempted Induction of Granulosa Cell Tumor in Balb-C Mice by Gonadotropin Administration.** (Eng) Menczer, J. (Dept. Obstetrics and Gynecology, Sheba Medical Center, Tel-Hashomer, Israel); Komarov, H.; Shenboun, M.; Insler, V.; Czernobilsky, B. *Gynecol Invest* 8(5/6): 314-322; 1977.

An attempt of granulosa cell tumor (GCT) induction by prolonged administration of exogenous pregnant mare's serum gonadotropin (PMSG) to young (21-day-old), mature (6-mo-old), and middle-aged (10-mo-old) BALB/c mice resulted mainly in stromal luteal cell proliferation. This proliferation occurred in 48.9% of young mice, 64.5% of mature mice, and 65% of middle-aged mice. The effect seemed to depend on duration of treatment in young mice. Young mice inoculated for < 6 mo developed significantly less luteal cell proliferation than those inoculated for > 6 mo. Only one GCT was found. This study supports the contention that besides gonadotropin stimulation, other factors may be involved in GCT development. A large number of PMSG-inoculated mice developed generalized lymphosarcoma, the mechanism of which remains unknown. (15 refs)

- 78-6345 Covalent Binding of Ethinylestradiol and Estrone to Rat Liver DNA In Vivo.** (Eng) Jaggi, W. (Inst. Toxicology, Federal Inst. Technology and Univ. Zurich, CH-8603 Schwerzenbach, Switzerland); Lutz, W. K.; Schlatter, C. *Chem Biol Interact* 23(1): 13-18; 1978.

The covalent binding of $6,7\text{-}^3\text{H}$ -ethinylestradiol (EE) and $6,7\text{-}^3\text{H}$ -estrone (E) to the liver DNA of fasted female Sprague-Dawley rats (190 to 240 g) was measured 8 hr after the administration of 80 μg (9.2 mCi) of the estrogens by gavage. Only 1% of the total radioactivity from EE was excreted in the urine within 8 hr; 4% of the radioactivity lyophilized as tritiated water. Three percent of the radioactivity from E was excreted in the urine within 8 hr, 3% of it as tritiated water. The binding of EE and E to the liver DNA was 1.5 and 1.1, respectively, expressed as binding to DNA/dose, in units of $\mu\text{moles hormone/mol DNA phosphate/millimoles hormone/kg}$. It was on the same order of magnitude as that for benzene and about 10,000-fold lower than that for typical liver carcinogens such as aflatoxin B₁ and N,N-dimethylnitrosamine. E and its ethinyl derivative should not differ with regard to their suspected carcinogenicity. (20 refs)

- 78-6346 Histometric Study of the Pituitary in Treated Neonatally with Steroids and the Relationship Between Prolactin Cells and Mammary Tumorigenesis.** (Eng) Kawashima, S. (Zoological Inst., Faculty of Science, Univ. Tokyo, Tokyo 113, Japan); Bern, H. A.; Jones, L. A.; Mills, K. T. *Endocrinol Jpn* 25(4): 341-348; 1978.

In female BALB/cfC3H/Crgl mice, neonatal hormone treatments had a significant effect on pituitary histology and mammary tumorigenesis. Within 36 hr after birth, mice were given five daily sc doses of 5 or 20 μg 17β -estradiol (E), 100 μg progesterone (PRG), or 5 or 20 μg ovine prolactin (PRL), singly or in various combinations. Pituitary glands were studied at autopsy upon tumor development or at 1 yr. Treatment with ESD (with or without PRL), PRG + ESD, or ESD + PRG resulted in significantly greater overall mammary tumor incidence, at a significantly earlier age, than in untreated controls. Pituitary PRL cells were more numerous in tumor-bearing mice vs non-tumor-bearing mice. Ovariectomy at day 40 markedly decreased the PRL cell count and abolished the effects of neonatal steroid treatment. Neonatal ESD (with or without PRL) and PRG treatment also resulted in significant decreases in gonadotropes. PRL alone had no such effect. There was correlation between gonadotropin levels and thyrotrope levels and mammary tumor incidence. These results suggest that neonatal steroid treatment stimulates mammary tumorigenesis through increased prolactin secretion. (34 refs)

- 78-6347 Induction of Ovalbumin Synthesis in Immature Chicks by Actinomycin D and Thioacetamide.** (Eng) Sharma, O. K. (Dept. Microbiology, Univ. Colorado Medical Center, Denver, CO, 80262). *Science* 202(4368-69): 1978.

The induction of ovalbumin synthesis and of an increase in serum progesterone (PG) levels in estrogen-treated immature chicks by thioacetamide (TAM) and actinomycin D (AMD) is reported. Four-day-old Calhorm chicks were inoculated with 1 mg estradiol benzoate in sesame oil for 10 days (primary estrogen stimulation). After 3-4 wk of estrogen withdrawal, with no ovalbumin synthesis being detectable, chicks were inoculated ip with TAM (0.25 mg/g/day x 3) or AMD (0.4 μg /g/day x 1). TAM-treated chicks were sacrificed after 3 days, AMD-treated chicks after 24 hr. Oviducts were removed, and ovalbumin synthesis in the oviductal lumen was determined. Labeled ovalbumin was measured by specific immunoprecipitation with monospecific antiserum against purified ovalbumin and confirmed by gel electrophoresis. Pooled serum was analyzed for PG by radioimmunoassay. TAM and AMD induced ovalbumin synthesis from undetectable percentages of total protein synthesis to 9.1% and 8.7%, respectively. Likewise, serum PG levels (nanograms/100 mg) were increased from 89 to 296 and from 40 to 317 in two TAM treatment trials and from 100 to 400 and from 81 to 496 in two AMD trials. PG induced by TAM and AMD may account for the induction of ovalbumin synthesis.

s. How carcinogens of different structures such as TAM and AMD increase serum PG remains to be elucidated. The hormone imbalance may have implications in the mechanisms of carcinogenesis. (27 refs)

348 Metabolism of Androgens and Estrogens by Human Fecal Microorganisms. (Eng) Lombardi, P. Infectious Disease Service, Dept. Medicine, Tufts-New England Medical Center, Boston, MA, 02111; Goldin, B.; Bou-E., Gorbach, S. L. *J Steroid Biochem* 9(8): 795-801; 1978.

metabolism of androgens and estrogens by human fecal microorganisms was studied in vitro at high and low fecal concentrations and under aerobic and anaerobic conditions. The reactions were run for 0-7 days at a fecal extract concentration of 50-60 or 6-10 mg/ml; the metabolites were extracted and purified, and steroids were identified by gas-liquid chromatography. In reactions at the high fecal concentration 5 β -3-ketosteroids were reduced to 5 β -3-hydroxysteroids and 17-ketoandrogens and estrogens were reduced to hydroxy products. A low fecal concentration resulted in products formed by oxidation and by cleavage of conjugated steroids: 5 β -androsterone-3,17-dione was converted to 4-androstene-3,17-dione, and 17 β -hydroxysteroids were converted to 17-oxosteroids. Estrogen-3-sulfate and estradiol-3-glucuronide were hydrolyzed to form estrone and estradiol, respectively. These results indicate that fecal concentration determines the types of metabolites formed. The reactions occurred under aerobic and anaerobic conditions. Their occurrence under aerobic conditions may reflect the ability of fecal extract to lower the oxidation-reduction potential of the reaction mixture. This study demonstrates that human intestinal flora can carry out a variety of reductive, oxidative, and hydrolytic reactions on androgens and estrogens. (21

349 Plasma Hormone Profiles of Young Women at Risk for Familial Breast Cancer. (Eng) Fishman, J. (Inst. Steroid Res., Montefiore Hosp. and Medical Center, Bronx, NY, 10467); Fukushima, D.; O'Connor, J.; Benfeld, R. S.; Lynch, H. T.; Lynch, J. F.; Guirgis, H.; Honey, K. *Cancer Res* 38(11, part 2): 4006-4011; 1978.

Plasma hormone profiles from 30 women at high risk for familial breast cancer and from their matched low-risk controls were analyzed. The case subjects were premenopausal, pubertal women without evidence of neoplastic disease with many close relatives with breast cancer or tumors associated with breast cancer and who, by genetic analysis, were at a clearly defined high risk for the disease. The controls were matched closely for height, wt, age, and reproductive history. Plasma hormone levels were measured every second day throughout the menstrual cycle, and the results were analyzed in terms of follicular, luteal, and full-cycle mean concentrations. There were no statistically significant differ-

ences in prolactin, follicle-stimulating hormone, luteinizing hormone, estrone, estradiol, or estriol levels between the two groups, although the high-risk group had consistently lower values of all these hormones except estriol. The mean plasma estriol levels in the follicular and luteal stages were 19.7 and 24.8 picograms/ml in the high-risk women and 23.5 and 23.1 picograms/ml in the controls. The results suggest that the etiology of female and male familial breast cancer is fundamentally different, since male relatives of male breast cancer patients had substantially elevated plasma estrogen levels. (26 refs)

78-6350 Phytoestrogen Interaction with Estrogen Receptors in Human Breast Cancer Cells. (Eng) Martin, P. M. (Institut J Paoli-I. Calmettes, 13273 Marseille, France); Horwitz, K. B.; Ryan, D. S.; McGuire, W. L. *Endocrinology* 103(5): 1860-1867; 1978.

The interactions of phytoestrogens with estrogen receptors (ER) were studied in the human breast cancer cell line MCF-7. When cytosol from MCF-7 cells was incubated with 4 nanomoles (nmol) ³H-estradiol and 400 nmol unlabeled phytoestrogens, all but one compound competed with estradiol for binding to nuclear and cytoplasmic ER. The relative binding affinities (followed by approx dissociation constants) were zearalenol high-melting point isomer (HP) (1 nmol) > zearalenol low-LMP (15 nmol) > zearalenone (6 nmol) = coumestrol (2 nmol) > genistein (10 nmol) > formononetin (2 μ M), which had little effect. The phytoestrogens bound only weakly to sex steroid-binding globulin and none bound to corticosteroid-binding globulin. When whole MCF-7 cells were incubated with 1 μ M genistein, coumestrol, and zearalenol HMP for 5 min to 15 hr, the cytoplasmic ER was depleted within 5 min, and the hormone-receptor complex was translocated to the nucleus. Zearalenol was as effective as estradiol in the ER translocation. The phytoestrogen-bound receptors were processed in the nucleus at about the same rate as estradiol-bound receptor. The plant estrogens, particularly coumestrol, were markedly enhanced during the log-phase growth of MCF-7 cells. These nonsteroidal compounds apparently function in the same manner as estrogen, and they may have profound effects on estrogen target cells. (41 refs)

78-6351 Impeding Estrogens and the Etiology of Breast Cancer. (Eng) Wotiz, H. H. (Dept. Biochemistry, Boston Univ. Sch. Medicine, Boston, MA, 02118); Chatteraj, S. C.; Kudisch, M.; Muller, R. E. *Cancer Res* 38(11, part 2): 4012-4020; 1978.

New data relevant to the action of estriol (E) and related impeding estrogens, obtained from several experiments, are presented. Synthesis of progesterone receptor, induced by 2-day treatment of Sprague-Dawley rats with estradiol (ED: 0.1 μ g/day/sc), was inhibited by simultaneous injection of 10 μ g/day E or 16-epiestriol. Silastic tubing implants con-

taining E (1 mg) markedly reduced breast tumor takes and delayed the onset of first tumors in rats treated 4 days later with 7,12-dimethylbenz(a)anthracene (3 mg every other day x 3, iv). In contrast, implants containing 1 mg ED appeared to increase the number of tumor-bearers and to accelerate the onset of first tumors. Administration to pregnant rats of antibody specific to ED or E during gestation days 11-14 resulted in a slight reduction in the number of offspring for anti-ED antibody but a nearly total loss of fetuses with anti-E antibody. The contraceptive function of E cyclopentyl ether (500 μ g/kg po, gestation day 1) was reversible when 1.2 μ g/kg ED, was injected sc on gestation day 4. Injection of freshly mated rats with up to 500 μ g/kg 2-hydroxyestrone sc did not result in any antiimplantational or estrogenic activity. However, topical insertion of Silastic tubing implants containing this steroid into rabbit uteri produced complete contraceptive effects. Multiple injections of 50 μ g 2-hydroxyestrone produced max uterine growth in immature and adult ovariectomized rats. The data suggest that E, although containing some estrogenic properties, must have a significantly different physiological role in cancer development and reproduction when present in appropriate admixture with ED. - 78-6352 Benign Liver Tumors and Oral Contraceptives.** (Eng) Aungst, C. W. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263). *NY State J Med* 78(12): 1933-1934; 1978.

A hepatic adenoma developed in two women (both aged 24) who had been taking oral contraceptives for up to 4 yr and in one woman (aged 52) who had been taking conjugated estrogens for menopausal symptoms for 3 yr. One of the young women had symptoms suggesting an amebic abscess. She also had a carcinoembryonic antigen level of 18.7 nanograms/ml, a finding that may have been fortuitous. (7 refs)

- 78-6353 Hepatocellular Carcinoma Associated with Oral Contraceptives.** (Eng) Menzies-Gow, N. (Central Middlesex Hosp., Acton Lane, London, England). *Br J Surg* 65(5): 316-317; 1978.

A primary hepatic tumor occurred in a 36-yr-old woman who had been taking oral contraceptives (norethisterone acetate 3 mg, ethinylestradiol 50 μ g) for 6 yr. The patient suffered also from anemia and lactic acidosis. A partial hepatectomy was performed, and a secondary mass of tumor-containing lymphatic tissue in the region of the celiac axis was also excised. The tumor was a well-differentiated hepatocellular carcinoma with highly vascular areas and evidence of vascular invasion. The secondary tumor was histologically similar to the hepatocellular carcinoma. This case is the first with histological evidence of secondary spread of a malignant tumor associated with oral contraceptives. (13 refs)

- 78-6354 Liver Adenoma Associated with Oral Contraceptive Pill Administration.** (Eng) Baker L. (Univ. Chicago, Box 400, 950 E. 59th St., Chicago, 60637); Paloyan, D.; Simonowitz, D.; Lipson, R. M. *A Dig Dis* 23(5, Suppl): 53s-58s; 1978.

The case of a 33-yr-old woman with liver adenoma in whom an elevated serum alkaline phosphatase level led to the diagnosis is reported. The patient had been taking an oral contraceptive, Ovulen 21 (0.1 mg mestranol and 1.0 mg ethynodiol diacetate) continuously for 11 yr. (43 refs)

- 78-6355 Hepatic Estrogen and Progesterone Receptors in an Estrogen-associated Hepatic Neoplasm.** (Eng) Macdonald, J. S. (Div. Medical Oncology, Vincent Lombardi Cancer Res. Center, Washington, DC, 20004); Lippman, M. E.; Woolley, P. V.; Petrucci, P. P.; Schein, S. *Cancer Chemother Pharmacol* 1(3): 135-138; 1978.

The presence of cytosol estrogen and progesterone binding proteins in an estrogen-associated hepatic neoplasm was determined. The patient was a 53-yr-old premenopausal Caucasian woman who had received weekly im injections of diethylstilbestrol for 1 yr to control menstrual irregularity, 23 months before diagnosis of a polyploid vascular hepatic tumor (8 cm), and daily doses of an oral contraceptive containing norethynodrel + mestranol for 3 mo, 5 yr before diagnosis. Histologically, the tumor was classified as a focal nodular hyperplasia of the liver. It was found to contain high-affinity receptors for estradiol (binding capacity, 47.9 fmol/mg protein) and progesterone (binding capacity, 1.5 femtomoles/mg protein), with the binding capacity of the former being three times greater than that of normal liver. These results are consistent with the hypothesis that a small portion of normal hepatic cells have relatively high concentrations of cytosol estrogen receptors; these receptors render the cells particularly susceptible to stimulation to a neoplastic state by estrogen. PHYSICAL CARCINOGENESIS

56 **Greater Promotion in Sister Chromatid Exchanges by Trimethylpsoralen than by 8-Meopsoralen in the Presence of UV-Light.** (Eng) Gaynor, (Dept. Dermatology, Yale Univ. Sch. Medicine, 333 St., New Haven, CT, 06510); Carter, D. M. *J Invest Biol* 71(4): 257-259; 1978.

8-methoxypsoralen (8-MOP) and 4,5',8-trimethylpsoralen (TMP) were compared with respect to their ability to promote sister chromatid exchanges (SCEs) in normal human lymphocytes exposed to UV light (365 nanomoles). With either chemical treatment, leukocytes had more SCEs than untreated controls. TMP consistently induced more SCEs per cell than did equal concentrations of 8-MOP. The increase in SCEs was proportional to drug concentration (3.23×10^{-7} or 10^{-8} M) and dose of UV light (0.3, 0.6, or 0.9 joule/cm²). Treatment with khellin plus UV light also caused a dose-dependent increase in the number of SCEs per cell; however, the number of SCEs was not increased at the higher concentrations of this drug. No chromosomal aberrations were observed with any of the treatments, but there were more mitoses in cells receiving higher doses of drug and longer exposures to UV light than in controls. The differences in the effects of 8-MOP and TMP on various cell functions may be related to qualitative and quantitative differences in the products they form. (22 refs)

57 **Nucleosome Rearrangement in Human Chromatin During UV-induced DNA Repair Synthesis.** Smerdon, M. J. (Dept. Pathology, Washington Univ. School of Medicine, St. Louis, MO, 63110); Lieberman, M. W. *Natl Acad Sci USA* 75(9): 4238-4241; 1978.

Nucleosome rearrangement was investigated in human diploid fibroblasts (IMR-90 cells) prelabeled with ¹⁴C-thymidine during the logarithmic phase, grown to confluence, treated with hydroxyurea, and irradiated with a UV dose of 100 J/m². Immediately after irradiation, the cells were chased with ³H-thymidine (10 or 90 min) and chased in non-radioactive medium for different times, and the distribution of UV-induced DNA repair synthesis in chromatin was measured. Immediately after irradiation, repair synthesis occurred primarily in staphylococcal nuclease-sensitive regions of chromatin. Subsequent incubation of cells in unlabeled medium resulted in the conversion of many of these repair sites to nuclease-resistant regions. Agarose gel data indicated that repair sites acquired nuclease resistance with the appearance in core DNA. Rearrangement also resulted in a more uniform distribution of repair sites in linker and core regions and not in an overrepresentation of repair sites in the latter. Rearrangement was both rapid and exten-

sive: at least 85% of the repair sites underwent rearrangement during the first few hours; the rest of the repair sites underwent rearrangement at a much slower rate. There was a striking correlation between the time course of rearrangement and repair synthesis, suggesting that nucleosome rearrangement may be induced by the repair process or that the rate of repair synthesis may be regulated by nucleosome rearrangement. 78-6358 **Molecular Mechanisms Involved in the Production of Chromosomal Aberrations. I. Utilization of Neurospora Endonuclease for the Study of Aberration Production in G2 Stage of the Cell Cycle.** (Eng) Natarajan, A. T. (Dept. Radiation Genetics and Chemical Mutagenesis, State Univ. Leiden, Wassenaarseweg 72, Leiden, Netherlands); Obe, G. *Mutat Res* 52(1): 137-149; 1978.

A study was made of the effect of Neurospora endonuclease (NE) on the induction of single-strand (ss) breaks in the G2 stage of the cycle of Chinese hamster ovary cells by x-rays, UV light, or chromosome-breaking chemicals. The enzyme was added in the presence of inactivated Sendai virus, which mediated the introduction of NE into living cells. NE is ss-specific and thus is expected to induce double-strand (ds) breaks in the ss regions of DNA. Addition of NE + virus immediately after treatment of the cells with 50-200 R x-rays more than doubled the frequencies of breaks and exchanges compared with x-irradiated controls. The effect was dose-dependent. This increase was due to the conversion of some of the x-ray-induced ss breaks into ds breaks by NE. NE + virus increased the number of aberrations produced by methyl methanesulfonate (0.01%) and bleomycin (10 µg/ml), but not those produced by UV light (10-50 ergs/mm²) or mitomycin C (mmc: 2 µg/ml). Addition of Micrococcus endonuclease and NE to the cells also did not alter the frequencies of UV-induced aberrations. The failure to convert UV- and MMC-induced lesions into aberrations in G2 indicated that these agents need an S-phase-dependent misreplication for aberration development. The study shows that the basic structure involved in chromosomal aberrations is DNA, ds breaks lead to chromosomal aberrations, and that the introduction of repair enzymes into living cells offers a way to probe into the molecular events of chromosomal aberration formation. 78-6359 **Effects of Chemical and Physical Mutagens on the Frequency of a Large Genetic Duplication in Salmonella typhimurium. I. Induction of Duplications.** (Eng) Hoffmann, G. R. (Natl. Inst. Environmental Health

Sciences, Research Triangle Park, NC, 27709); Morgan, R. W.; Harvey, R. C. *Mutat Res* 52(1): 73-80; 1978.

A simple selection procedure for detecting *Salmonella typhimurium* strains that are merodiploid (MD) for almost one-third of the chromosome is based on improved utilization of L-malate as the sole carbon source in MD strains. The spontaneous frequency of the duplication in haploid strains is approx 10^{-4} per cell plated. Following the exposure of a haploid strain to mutagenic agents, there is a dose-dependent increase in the duplication frequency above the spontaneous level. X-rays, UV light, ethyl methanesulfonate, nitrous acid, and the azaacridine half-mustard ICR-372, a group of mutagens that have a variety of different molecular mechanisms of action, induced genetic duplications. It is concluded that this effect in bacteria may be a consequence of the recombination of mutagenic agents analogous to that previously noted in yeasts. (32 refs)

78-6360 Effects of Chemical and Physical Mutagens on the Frequency of a Large Genetic Duplication in *Salmonella typhimurium*. II. Stimulation of Duplication-Loss from Merodiploids. (Eng) Hoffmann, G. R. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Morgan, R. W.; Kirven, R. *Mutat Res* 52(1): 81-86; 1978.

Strains of *Salmonella typhimurium* (ST) that contain a duplication of approx 30% of the genome may be obtained by a simple selective procedure. These strains are very unstable, losing the duplication when grown on nonselective medium. The system used to detect duplication formation and loss is based upon clone morphology and rates of growth on L-malate. Most *Salmonella* derived from wild-type strain LT2 grow very poorly on medium in which L-malate is the sole carbon source, but merodiploid (MD) derivatives of these bacteria exhibit improved growth on minimal malate medium. MD's are also distinguishable from haploids by of their characteristic rough colony morphology on minimal malate or minimal glucose medium. Treatment of MD bacteria with mutagenic agents stimulated the rate at which haploid segregants were obtained from MD strains. The mutagens tested for this effect were x-rays, UV light, ethyl methanesulfonate, and the azaacridine half-mustard ICR-372. Although other models for the induction of duplication loss in MD *Salmonella* strains cannot be ruled out, the variety of molecular mechanisms of genetic activity exhibited by these mutagens point to a recombinational effect analogous to induced mitotic recombination in yeasts. 78-6361 Does Ultraviolet Light Enhance Postreplication Repair in Mammalian Cells? (Eng) Painter, R. B. (Lab. Radiobiology, Univ. California, San Francisco, CA, 94143). *Nature* 275(5677): 243-245; 1978.

The results of a previous study in which Chinese hamster cells were exposed twice to UV and their DNA was analyzed by alkaline sucrose gradient velocity sedimentation were confirmed, but an alternative interpretation of the data is presented. The previous work postulated the existence of an enhanced postreplication repair system to explain the altered pulse-chase profiles observed for the DNA of mammary cells irradiated with 2.5 joules (J)/m² of UV light 2 hr before a second exposure to 5.0 J/m². If the profiles are plotted as total radioactivity per fixed number of cells, the inhibition of DNA synthesis caused by each treatment is demonstrated. Analysis of profiles of both pulse-labeled and pulse-chase DNA indicated that cells exposed to 2.5 J/m² had not recovered from the damage in their DNA by 2.5 hr after irradiation. The status of nascent DNA molecules in these cells was not the same as in controls; although the mol wt of the nascent DNA molecules was lower in treated cells than in control cells, a significant number of these molecules had a higher mol wt. Thus, the effects of 5.0 J/m² of UV light on DNA synthesis and of maturation of nascent Chinese hamster V79 DNA are different in cells that were irradiated earlier with 2.5 J/m² than in previously unirradiated cells. These differences can be explained entirely by the damage effects of the first exposure, which cause an abnormal distribution of sizes of nascent DNA molecules at the time of irradiation with 5.0 J/m². (4 refs)

78-6362 Chromosome Damage and DNA Repair Induced in Human Fibroblasts by UV and Cholesterol Oxide. (Eng) Parsons, P. G. (Queensland Inst. Medical Research, Herston, Queensland, Australia); Goss, P. *Aust J Exp Med Sci* 56(part 3): 287-296; 1978.

Attempts were made to transform normal melanoma-derived human fibroblasts using UV light, cholesterol oxide (ChO), and hyperthermia (40 C), singly or in combination. Chromosome and DNA damage was monitored along with transformed foci. No evidence of transformation was obtained after any of the treatments. Chromosome aberrations were induced by UV light (9.8%) and ChO (8.1%) alone, and the number of aberrations was increased to 13%-20% when hyperthermia was combined with ChO and/or UV light and to 15% when ChO and UV light were combined. All the induced aberrations were still present after 8 wk. Aberration frequencies were not significantly increased by multiple as opposed to single UV light treatment. UV light and ChO also induced DNA repair synthesis, and the former but not the latter, induced single-strand breaks and inhibited thymidine incorporation. The data suggest that factors synergistic to the later stages of carcinogenesis might be effective long after UV exposure. (22 refs)

78-6363 Anaplastic Thyroid Carcinoma Following Low-Dose Irradiation. (Eng) Komorowski, A. (Dept. Pathology, Medical Coll. Wisconsin, 8700 W. Wisconsin Ave., Milwaukee, WI, 53226); Hanson, G. A.; Gajdos, J. C. *Am J Clin Pathol* 70(2): 303-307; 1978.

2-yr-old man underwent surgical removal of a metastatic, well-differentiated papillary adenocarcinoma of the thyroid gland after treatment with low-dose irradiation for adenoid cystic carcinoma. Fifteen months later, an enlarged cervical node prompted a second surgical exploration and a modified, radical neck dissection was performed. Histologic examination revealed that a portion of the lesion was identical to the original tumor but that the majority of the lesion was an anaplastic thyroid cell tumor. Five of the 60 lymph nodes in the dissection contained well-differentiated papillary carcinoma. Three months postoperatively, 0.5 cm nodules were again palpated in the left neck. It appears that radiation-induced thyroid carcinomas, in at least a very small number of people, may be associated with aggressive carcinoma. (14 refs.)

6364 **Apurinic and/or Apyrimidinic Endonuclease Activity in Ataxia Telangiectasia Cell Extracts.** (Eng) Sheridan, R. B. (Dept. Biochemistry, Johns Hopkins Univ., Sch. Hygiene and Public Health, 615 N. Wolfe St., Baltimore, MD, 21205); Huang, P. C. *Mutat Res* 52(1): 131-136; 1978.

A hypothesis that a defective repair mechanism for ionizing radiation-induced DNA damage is associated with ataxia telangiectasia (AT) was investigated with the use of six APU/APY three control lines. The base excision repair mechanism involving the apurinic and/or apyrimidinic endonuclease (Apu/APY EN) responsible for incision at the site of base loss was examined in a nicking assay for Apu/APY activity using double-stranded, covalently closed, supercoiled Φ X174 RFI DNA modified to produce an average of one Apu site/molecule. There was no statistical difference in acid phosphatase levels (chosen as an internal control) between the AT and control lines, but Apu/APY EN activity was slightly reduced in the former (15 units, vs 214 units in control lines). However, even the lowest level of activity seen was far in excess of that detected by a growing cell. Next, the extent of incision by the Apu/APY EN of each of the cell lines was measured as a function of increasing amounts of damage in the substrate. As the number of Apu sites increased, both control and AT lines appeared capable of incising all those present. Thus, AT cells complete the incision step to the same extent as controls, even with 22% less enzyme activity. It is concluded that a deficiency in base excision repair at the level of the APU/APY specific for the site of base loss is probably not an explanation for AT. (24 refs)

6365 **Fatal Long-Term Sequela Following Radiation "Cure" for Ependymoma.** (Eng) Bachman, D. (Johns Hopkins Hosp., Baltimore, MD); Ostrow, P. T. *Ann Neurol* 4(4): 319-321; 1978.

A case of glioblastoma or severe radiation-induced encephalopathy occurred at the site of an ependymoma that had been treated by radiotherapy 5 yr previously. The patient, a 4-yr-old child, had been treated at age 13 mo with 3,960 rads to the whole brain over 6 wk followed by 2,300 rads to the spinal

cord over 6 wk. It seems likely that the changes were radiation-induced. (11 refs)

78-6366 **Non-enzymatic DNA Strand Breaks Induced in Mammalian Cells by Fluorescent Light.** (Eng) Bradley, M. O. (Lab. Molecular Pharmacology, Developmental Therapeutics Program, Div. Cancer Treatment, NCI, NIH, Bethesda, MD, 20014); Erickson, L. C.; Kohn, K. W. *Biochim Biophys Acta* 520(1): 11-20; 1978.

The relationship between the mutagenicity and toxicity of fluorescent light and the production of DNA damage was examined in male Chinese hamster lung (V-79-4) cells. The cells were irradiated with 5.4 joules/m²/sec of fluorescent light in complete medium at 1 C for 1, 2, or 3 hr. The light induced 0.041 single-strand break/10⁶ daltons/hr in the DNA of the cells (4.8×10^{-6} break/10⁶ daltons/joule⁻¹m²). The breaks were unrelated to pyrimidine dimers and were also apparently distinct from previously described chemically induced alkaline-sensitive lesions. They were presumably generated by nonenzymatic mechanisms, as shown by the facts that (1) the breaks were produced at 1 C, a temperature at which most enzymatic reactions are slow; (2) the number of breaks remained constant at 1 C for 2 hr after illumination, showing no delay between illumination and break production; and (3) the breaks were produced by fluorescent light in DNA isolated from cells that were lysed and deproteinized under conditions in which no enzymes should survive. The light probably produced the breaks by a nonenzymatic mechanism either directly in the DNA itself or by the action of some unknown sensitizer. When the cells were incubated at 37 C, the breaks rejoined within 2 hr. At least two lesions were responsible for the observed effects. One had the ability to break DNA subsequently treated with alkali but was neither toxic nor mutagenic. This lesion was due to > 350-nanometer (nm) light. The other lesion(s) produced mutagenicity and/or toxicity but did not necessarily produce strand breaks. This lesion(s) was due to < 350-nm light. (21 refs)

78-6367 **The Determination of Plutonium in Tissue by Aliquat-336 Extractions.** (Eng) Fisenne, I. M. (Environmental Measurements Lab., U.S. Dept. Energy, New York, NY, 10014); Perry, P. M. *Radiochem Radioanal Lett* 33(4): 259-264; 1978.

A rapid, reproducible method based on solvent extraction was developed to separate plutonium from environmentally exposed human tissue. Tetravalent Pu was extracted from 8.5 N HNO₃ into a 30% Aliquat-336 (methyl tricaprylyl ammonium chloride)/toluene mixture. Uranium and thorium were removed by nitric and hydrochloric acid washes, and the Pu was back-extracted with an HCl-HF soln. Electrodeposition of Pu from an acidic ammonium sulfate soln produced a plate suitable for alpha spectrometry. The amount of Pu recovered from samples of human lung, bronchial tree, and bone was 70%-80%, indicating that the

chemical yield was consistent regardless of tissue type or wt of tissue analyzed. (6 refs)

- 78-6368 **The Use of Transposable Genetic Elements in *Drosophila melanogaster* as a Fast and Sensitive System for Mutagenicity Testing (Meeting Abstract).** (Eng) Rasmuson, B. (Dept. Genetics, Univ. Umea, S-901 87 Umea, Sweden); Svahlin, H.; Rasmuson, A.; Montell, I.; Olofsson, H. *Mutat Res* 53(2): 252; 1978. (no refs)

- 78-6369 **$^{239}\text{PuO}_2$ Aerosol Inhalation Exposure of Miniature Swine.** (Eng) Karagianes, M. T. (Biology Dept., Battelle, Pacific Northwest Labs., Richland, WA, 99352); Beamer, J. L.; Clary, A. J.; Craig, D. K.; Decker, J. R.; Cannon, W. C. *Radiat Res* 74(1): 79-87; 1978.

Because of the anatomic and physiological similarities between swine and humans, techniques were developed for the inhalation exposure of miniature swine to radioactive aerosols to determine the biological effects of $^{239}\text{PuO}_2$. Anesthetized animals were exposed to $^{239}\text{PuO}_2$ aerosols in dog inhalation chambers that had been modified to accommodate the swine. A sling cart for transporting and restraining the pigs and special face masks to allow intranasal exposure only were designed and fabricated. Four swine were exposed to aerosols consisting of 20 mg ^{239}Pu /ml water and an air mixture of 5:1. Two swine were exposed to aerosols having an activity median aerodynamic diameter (AMAD) of $3.0\text{ }\mu\text{m}$ and a geometric standard deviation (GSD) of 2.1, and two were exposed to aerosols with an AMAD of $2.0\text{ }\mu\text{m}$ and a GSD of 1.8. The pigs were killed at 10, 13, 30, and 90 days postexposure. Pu was cleared from the body in a biphasic pattern, with a biological retention half-time of a few days for 90% of the initial alveolar burden and ≥ 50 days for the remainder. There was very little transfer of Pu to the systemic organs: 83%-96% of the Pu retained in the body at necropsy was in the lung and pulmonary lymph nodes. (20 refs)

- 78-6370 **Frequency of α -Particles from $^{239}\text{PuO}_2$ in Lung Cells.** (Eng) Kellerer, A. M. (Institut fur Medizinische Strahlenkunde der Universitat Wurzburg, Versbacher Landstrasse 5, D-8700 Wurzburg, W. Germany). *Radiat Environ Biophys* 15(11): 13-19; 1978.

Mathematical considerations of the effect of $^{239}\text{PuO}_2$ particles in the lung are presented. If a given activity is uniformly dispersed, a max number of cells will be traversed by α -particles and the probability of multiple traversals of one cell will be small. However, if the activity occurs in $^{239}\text{PuO}_2$ particles, the cells close to these particles will be subject to multiple traversals and the number of cells at risk will be reduced. Furthermore, malignant transformations produced by the α -particles are less likely to be expressed because it is unlikely that multiply traversed cells will retain their proliferative capacity. It is thus concluded that a given activity will be less effective when it occurs in $^{239}\text{PuO}_2$ particles. (4 refs)

- 78-6371 **Endonuclease Activities from a Permanent Established Mouse Cell Line that Act on DNA Damaged by Ultraviolet Light, Acid and Osmium Tetroxide.** (Eng) Nes, I. F. (Dept. Biochemistry, Univ. Bergen, Arstadveien 19, 5000 Bergen, Norway); Nissen-Meyer, M. *Acta Biochim Biophys Acta* 520(1): 111-121; 1978.

Damage-dependent endonuclease activities in cell-free extracts from mouse plasmacytoma cells (line MPC-11) were characterized using ϕ x 174 RFI DNA damaged by UV light ($1,000\text{ joules/m}^2$), acid, or osmium tetroxide. The extracts produced approx 1.1 nicks per 35 thymine-containing dimer in the UV-damaged DNA. The acid-treated DNA, which contained apurinic sites, was enzymatically broken at every kali-labile site. The extract was shown to contain an apurinic-specific endonuclease that was stimulated by magnesium, stimulation being lower for the UV-endonucleolytic activity than for the apurinic-endonucleolytic activity. Also, when the UV-endonuclease activity was little affected by reducing the KCl concentration, the apurinic-specific activity was most completely abolished. DNA exposed to increasing concentrations of OsO_4 (to $80\text{ }\mu\text{g/ml}$) became a progressively better substrate for the endonucleolytic activity. The response of the OsO_4 -specific endonuclease activity to KCl and Mg was qualitatively similar to that of the endonuclease activity that acted on UV-irradiated DNA. The results suggest that one enzymatic activity recognized both OsO_4 and UV-induced lesions in DNA (ie, pyrimidines with a saturated double bond). (24 refs)

- 78-6372 **Effect of DL-Tryptophan on Plastic-induced Tumorigenesis.** (Rus) Pliss, G. B. (Lab. Chemical Carcinogens, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Eliseev, V. V. *Biull Eksp Biol Med* 86: 353-356; 1978.

The effect of DL-tryptophan (Try) on plastic carcinogenesis was studied in random-bred albino rats. A copolymer of methyl and ethyl ester of methacrylic acid was implanted in the form of a powder or plate, into the rats: 800 mg of powder was implanted into the right side and a 20- x 20- mm plate was implanted into the left side. On the next day the rats were divided into two groups: 34 rats in Group 1 received Try in sunflower oil (100 mg/day, 5x/wk, po), and 32 rats in Group 2 received sunflower oil only (0.5 ml/d, 5x/wk). In Group 2, the first acrylic plate-induced tumors were detected 12.3 mo after transplantation: 11/27 survivors developed fibrosarcomas after an av latent period of 11.3 mo. Implantation of the acrylic powder did not induce tumors. In Group 1, the first acrylic plate-induced tumors were detected 13.8 mo after transplantation: 6/19 survivors developed fibroblastic sarcomas (av latent period was 16.3 mo). Contrary to the Group 2 rats, two rats in Group 1 developed a fibrosarcoma at the site of acrylic powder implantation at 18.7 mo. (11 refs)

373 **Late Effects of Successive Massive Doses of Radiation on Parabiont Rat Pairs.** (Eng) War-S. (Cancer Res. Inst., New England Deaconess Hosp., Boston, MA, 02215); Chute, R. N.; Porter, M. W.; Brown, J. *Int J Radiat Biol* 34(3): 265-271; 1978.

Study was made of the life-span and leukemia and osteogenic sarcoma incidence in pairs of parabiont rats that survived 1,000-R doses of whole-body radiation, given first to one partner and then to the other after intervals of 5, 10, and 30 days. The degree of recovery and of residual damage in the first irradiated rat was measured by the extent of its ability to support its subsequently exposed partner. Life-span was shortened by 100-150 days following a 5-day interval and by 200-300 days following a 10-day interval, but it was not shortened following a 30-day interval. The incidence of leukemia (1.7%) was the same in sequentially irradiated groups, regardless of the time between exposures; the incidence of leukemia in control pairs was 4.8%. Shortening the interval between irradiations decreased the average age at death from leukemia; leukemic pairs had an average age at death of 690 days for those irradiated 30 days apart, 490 days for those with a 10-day interval, and only 325 days for those with a 5-day interval. None of the pairs in which both partners were irradiated developed solid lymphoid tumors. The incidence of osteogenic sarcoma (including lesions occurring in soft parts) in the parabiont pairs in which both partners were irradiated sharply increased to 12.9%, or about 8 times the rate in non-irradiated controls (1.6%), 2 times that in pairs in a hemi-irradiated series (7.0%), and 9 times that in shielded partners in the hemi-irradiated series (1.4%). (14 refs)

6374 **Radiation-induced Soft-tissue and Bone Sarcoma.** (Eng) Kim, J. H. (Dept. Radiation Therapy, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Chu, F. C.; Woodard, H. Q.; Melamed, M. R.; Vos, A.; Cantin, J. *Radiology* 129(2): 501-508; 1978.

The records of a single hospital over the past 50 yr revealed 10 cases of soft-tissue sarcoma arising from irradiated tissues and 27 cases of radiation-induced bone sarcoma. The patients with soft-tissue sarcomas ranged in age at the time of initial treatment from 7 to 44 yr, the mean and median latent period from first irradiation to the discovery of sarcoma being 12 and 16 yr, respectively. Nine of these patients were irradiated for benign conditions, 10 were irradiated for malignancies, and one was occupationally exposed to radiation. The patients with bone sarcomas ranged in age from 1 to 56 yr, the mean and median latent period from first irradiation to the discovery of sarcoma being 11 and 12 yr, respectively. Two patients were irradiated for benign conditions and 25 were irradiated for malignancies. Twenty-four additional cases of radiation-induced osteogenic sarcoma found in the literature resembled the current patients in sex ratio, radiation dose, and induction time. The median nominal standard doses of radiation associated with the soft-tissue and bone sarcomas were 1900 and 2270 rets (rads-equivalent-therapeutic), re-

spectively. No radiation-induced tumors were seen at doses below 1100 rets. For the bone sarcomas, the latent period was longer after larger radiation doses; and children appeared to be more susceptible to the development of cancer than did adults. (30 refs)

78-6375 **Chronic Mechanical Trauma in the Aetiology of Oro-pharyngeal Carcinoma.** (Eng) Thumfart, W. (Universitäts-HNO-Klinik, Waldstrasse 1, D-8520 Erlangen, W. Germany); Weidenbecher, M.; Waller, G.; Pesch, H. *J. J Maxillofac Surg* 6(3): 217-221; 1978.

The etiology of oropharyngeal carcinoma was studied in 86 patients with tumors of the oral cavity. Tumors of the gum and palate accounted for 62% of these tumors. Most (83%) of the patients were smokers and 49% regularly consumed alcohol, some to excess. In 44% of these patients, there was a coincidence of the cancer site with the site of persistent mechanical irritation by sharp teeth edges, prominent parts of an ill-fitting denture, or similar mechanical factors. Most of the tumors were keratinizing, poorly differentiated, squamous cell carcinomas, and all carcinomas in contact with a mechanical irritation had a surrounding wall of chronic inflammatory infiltration. Dysplasias of different degrees were found in the areas around the carcinomas. (16 refs)

78-6376 **Natural History of Radiation-associated Thyroid Cancer.** (Eng) Roudebush, C. P. (Thyroid Study Unit, Dept. Medicine, Univ. Chicago, Box 138, 950 E. 59th St., Chicago, IL, 60637); Asteris, G. T.; De Groot, L. *J. Arch Intern Med* 138(11): 1631-1634; 1978.

The clinical courses of 91 thyroid cancer patients who had received x-ray therapy (IR) between 1950 and 1975 were compared with those of a control group of thyroid cancer patients who had not received radiation therapy (RT). Although the two populations displayed similar profiles, several differences were apparent. In RT cases, the mean age was lower (28.2 yr vs 36.5), and, perhaps due to this, cervical adenopathy occurred more frequently (38.4% vs 25.4%). Treatment of RT patients had been more aggressive; more had total or near-total thyroidectomy (72.5% vs 56.9%) or received radioactive iodide (41.8% vs 21.9%). Primary papillary tumors were common in the RT group (87.8%). No anaplastic or medullary tumors were found, but invasive or metastatic disease (9.9% vs 4.2%) and multifocal disease (46.5% vs 15.9%) were more prevalent in these subjects. Moreover, recurrences were more common in the RT group (6.6% vs 1.4%). The death rate was similar in both groups. Parathyroid adenomas were observed in three irradiated patients, but none occurred in the controls. (20 refs)

78-6377 **Thyroid and Parathyroid Lesions after Radiation (Letter to Editor).** (Eng) Knights, E. M.

(South Macomb Hosp., Warren, MI, 48093); Phillips, E. *Ann Intern Med* 89(5, part 1): 725-726; 1978.

A 53-yr-old woman was found to have a solitary parathyroid adenoma, a papillary adenocarcinoma of the thyroid, and a colloid nodule of the thyroid. She had been treated with radiotherapy for acne at age 18. (3 refs)

- 78-6378 Radiation-induced Thyroid Carcinoma Following Treatment for Fetal Medulloblastoma.** (Pol) Borejko, J. (Klinika Radioterapii, Instytut Radiologii AM, Warsaw, Poland); Jeleniewska, A. *Pol Przegl Radiol* 42(3): 231-235; 1978.

Two patients (a girl and a boy aged 8 yr), received conventional radiotherapy for medulloblastoma. The girl received total doses of 2,500 and 2,800 R on two fields and an additional 3,300 R for a recurrence 5 yr later. She developed papillary carcinoma of the thyroid gland 16 yr after the first irradiation. The boy received a total dose of 3,500 R in 35 sessions in 67 days. He developed a mixed (papillary and follicular) thyroid carcinoma with metastases 10 yr later. (20 refs)

- 78-6379 Occurrence of Previous Neck Radiotherapy among Patients with Associated Non-medullary Thyroid Carcinoma and Parathyroid Adenoma or Hyperplasia.** (Eng) Tisell, L. E. (Dept. Surgery II, Sahlgren's Hosp., S-41345 Goteborg, Sweden); Hansson, G.; Lindberg, S.; Ragnhult, I. *Acta Chir Scand* 144(1): 7-11; 1978.

The medical records of 10/16 consecutive patients (12 women, 4 men) with coexistent primary hyperparathyroidism (HPT) and nonmedullary thyroid carcinoma revealed history of prior external radiation treatment to the neck. The ages at the time of first irradiation ranged from 2 mo to 51 yr (mean, 18 yr). The time lapse between first exposure and diagnosis of HPT and thyroid carcinoma ranged from 14 to 47 yr (mean, 36 yr). The thyroid tumor was limited to the gland in eight patients (Stage I). Regional lymph node metastases without concomitant cancer growth beyond the thyroid capsule were found in six patients (Stage II). In two patients, the tumor involved adjacent structures (Stage III); one of these patients also had lymph node metastases. The thyroid carcinoma was multifocal in four patients. There were 13 patients with a single parathyroid adenoma: in 8, a rim of compressed normal parathyroid tissue was found at the periphery of the adenoma; in 3, the removed parathyroid glands showed hyperplasia. In some of the enlarged parathyroid glands, hemorrhages as well as zones of fibrosis were present. Microscopically, the enlarged parathyroids in irradiated patients were similar to those of nonirradiated patients. The results agree with the hypothesis that radiation can serve as an etiological factor in the development of associated thyroid carcinoma and HPT. (17 refs)

- 78-6380 Radiation-induced Cancers in the Head and Neck Region.** (Jpn) Miyahara, H. (Dept. Otolaryngology, Kumamoto Univ. Sch. Medicine, H. Kumamoto 860, Japan); Matsuoka, H.; Ohbuchi, M.; Tani, M.; Sato, T.; Maeda, K. *J Otolaryngol Jpn* 81(3): 233-238; 1978.

A survey was made of 54 cases of radiation-induced cancer in the head and neck region. In 37 patients, the radiation had been applied as therapy for benign diseases, including 14 cases of tuberculous cervical lymphadenitis and 3 cases of dermal disease; in 14 patients, the radiation had been applied to treat malignant tumors, including 9 in the larynx and 5 in the thyroid. Among the radiation-induced cancers, there were 23 hypopharyngeal tumors, 14 thyroid tumors, and 17 cervicoesophageal tumors. Patients irradiated for malignant tumors had shorter intervals between treatment and development of radiation-induced cancer (av, 9.4 yr) than patients treated for benign conditions (av, 33 yr). Most of the tumors were well-differentiated squamous cell carcinomas of the pharynx and larynx; there were also 14 papillary and follicular adenocarcinomas of the thyroid gland and 1 fibrosarcoma of the upper lip. Studies show that the incidence of radiation-induced cancer is increasing. (16 refs)

- 78-6381 Promotion of Metastasis of C3H Mouse Mammary Carcinoma by Local Hyperthermia.** (Eng) Walker, A. (Glasgow Inst. Radiotherapeutics and Oncology, Belvidere Hosp., London Rd., Glasgow G31 4PG, Scotland); McCallum, H. M.; Wheldon, T. E.; Nias, A. H.; Abde, A. S. *Br J Cancer* 38(4): 561-563; 1978.

The response to hyperthermia of an infrequently metastasizing transplantable mammary carcinoma that originally arose spontaneously in C3H mice was investigated. Using a water heater that transfers heat via a thin membrane, heat was applied to 5- to 7-mm dorsal tumors in a temperature range of 42-46°C and a time range of 1-2 hr, time-temperature combination sufficient to eradicate the primary tumor. Fifty mice had their tumors locally controlled at 100 days of observation; time of death or sacrifice, if earlier. Of these mice, 7 died unexpectedly prior to routine autopsy and 14 were autopsied because of unexpected early death or physical deterioration. All 14 autopsied mice were found to have pulmonary metastases and, in some cases, metastases at other sites (4 to kidney, 3 to brown fat, and 1 each to heart, diaphragm, spleen, and lymph node). Taking only the proved metastases, the minimum rate for metastasis in this group was 14%, which may be contrasted to the max rate found previously in 14/131 mice whose tumors were locally controlled by radiation. (11 refs)

- 78-6382 Tumors in Animals Irradiated During Embryogenesis.** (Rus) Strel'tsova, V. N. (No affiliation given); Pavlenko-Mikhailov, Iu. N. *Vopr Onkol* 24(9): 25-28; 1978.

effect of irradiation during embryogenesis on tumor development was studied in male and female white rats whose fathers were irradiated with a single ^{60}Co dose of 100 rads (dose rate, 168 rads/min) on gestation days 7, 14, or 19. The animals that died at age 200-600 days were evaluated. The tumor induction rate was 184/219 vs 9/53 controls. The tumors included 52 breast tumors, 42 cases of leukemia, 53 lymphoid tumors, 11 ovarian tumors, 4 adrenal tumors, 3 thyroid tumors, 3 lung tumors, 3 bone tumors, and 1 tumor of the skin, uterus and intestine. The tumor incidence that occurred after irradiation during the embryonal (day 7) and fetal (day 19) periods was 69/107 and 44/70, respectively. Eighteen of the 42 animals irradiated during organogenesis (day 14) developed tumors by day 400, but animals irradiated during the embryonal and fetal periods developed tumors by days 120-180. The incidence of new tumors was highest during the last third of the life-span. Male rats irradiated during embryogenesis developed mammary gland and bone tumors, and females developed ovarian and bone tumors; these tumors were not seen in the controls. (12 refs)

6383 **Bilateral Pleural Thickening: A Manifestation of Asbestos Dust Exposure.** (Eng) Sargent, E. (Dept. Radiology, Los Angeles County-Univ. Southern California Medical Center, 1200 N. State St., Los Angeles, CA 90033); Gordonson, J.; Jacobson, G.; Birnbaum, W.; Hub, M. *Am J Roentgenol* 131(4): 579-585; 1978.

Forty-six asymptomatic patients with radiologic evidence of pleural thickening were discovered to have been occupationally exposed to asbestos dust, although this fact was clinically unsuspected. Pleural thickening most frequently involved the lower lung fields and was max at the level of the fifth through eighth ribs and costophrenic angles. There was no associated involvement of the parenchyma of the lung or the costophrenic angles. Most (67%) of the patients showed thickening up to 5 mm wide, and 8% showed thickening > 10 mm wide. The extent and severity of the pleural thickening did not correlate with the total duration of or time elapsed since asbestos exposure. Pleural thickening or plaques with no other evidence of disease in a relatively asymptomatic patient is a sign of possible exposure to asbestos dust. When retrospectively correlated with a lifetime occupational history, bilateral pleural thickening might serve as an indicator of asbestos dust exposure in the general population. (23 refs)

6384 **Renal Cell Carcinoma Following Radiation Therapy for an Adrenal Cortical Carcinoma.** (Eng) Andler, W. (Dept. Pediatrics, Univ. Essen, Hufelandstr. 55, D-4300 Essen 1, W. Germany); Havers, W.; Ambolis, C.; Medrano, J.; Stollmann, B. *J Pediatr* 93(4): 4-636; 1978.

The occurrence of renal cell carcinoma in an 11-yr-old girl approx 10 yr after radiation therapy for an adrenal cortical carcinoma is reported. The renal cell carcinoma was in all likelihood a direct consequence of the radiation therapy. (10 refs)

78-6385 **Influence of Misonidazole on the Incidence of Radiation-Induced Intestinal Tumours in Mice.**

(Eng) Rostom, A. Y. (Regional Centre Radiotherapy and Oncology, St. Lukes Hosp., Warren Road, Guildford, Surrey GU1 3NT, England); Kauffman, S. L.; Steel, G. G. *Br J Cancer* 38(4): 530-536; 1978.

The combined effects of misonidazole (MSD: 1 mg/g ip) and abdominal radiation in the range 16-24 Gray (Gy) units (1 unit = 100 rads) were studied in male C57BL mice. Eighty-one of 105 mice given radiation alone survived 50 days or longer, as did 81/106 mice sensitized with MSD 45 min before irradiation. Although the proportion of mice developing intestinal adenocarcinomas was similar in the two groups (60% and 68%, respectively) the incidence of multiple tumors was significantly higher in the MSD group (41% vs 18%). The av number of tumors per mouse was higher in the MSD groups at every radiation level, but the difference in the MSD and irradiation-only groups was most marked at a 20 Gy dose. With radiation alone, the most common tumor site was the cecum (49% of tumors) followed by the rectum (27%). MSD treatment reduced the cecal tumor incidence (37%), but it increased the rectal tumor incidence (40%). Most of the adenocarcinomas were mucin-secreting and located in regions of radiation damage. Although MSD may sensitize normal intestinal cells to the carcinogenic effect of radiation, these results do not call into question its present clinical use. However, there is the possibility that chemical radiosensitizers could enhance the incidence of second cancers in patients responding to radiotherapy. (15 refs)

78-6386 **Scenarios of ^{14}C Releases from the World Nuclear Power Industry from 1975 to 2020 and the Estimated Radiological Impact.** (Eng) Killough, G. G. (Health and Safety Res. Div., Oak Ridge Natl. Lab., Oak Ridge, TN); Till, J. E. *Nucl Saf* 19(5): 602-617; 1978.

Radioactive ^{14}C is formed as a by-product of nuclear power generation and a part is released to the environment. Estimated releases of ^{14}C from presently operating nuclear power facilities are still quite small in comparison with natural and other man-made sources, but potential growth in world demand for power will raise the quantity produced and released. The radiation dose to world population from natural and man-made ^{14}C is calculated based on three possible scenarios: (1) A pessimistic scenario (P) in which all the ^{14}C projected to be produced in fuel cycles is released. (2) An optimistic scenario (O) that assumes a decontamination fac-

tor of 100 for fuel reprocessing. (3) An intermediate scenario (I) that simulates a phased improvement in effluent treatment technology. The P scenario projects a ^{14}C release rate by the nuclear industry that exceeds natural production after the year 2000. The O and I scenarios project that ^{14}C release from the nuclear industry would attain a stationary level at approx 37% of natural production by 2020. Potential effects on the incidence of cancers and genetic disorders are calculated for the three scenarios from risk factors for exposure to ionizing radiation and ^{14}C specifically estimated by the International Commission on Radiological Protection. Total number of cancers and genetic effects over infinite time (effectively 46,000 yr or about eight half-lives of ^{14}C) are given for each of the three scenarios. For the O and I scenarios the cumulative potential health effects are about 22% of those from natural ^{14}C formed from 1975-2020, about 6% of those from

weapons testing, and $<0.04\%$ of those from natural already in the environment. (45 refs)

VIRAL CARCINOGENESIS

6387 Identification of Nucleotide Sequences Which May Encode the Oncogenic Capacity of Avian Retrovirus MC29. (Eng) Sheiness, D. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Fanshier, L.; Shop, J. M. *J Virol* 28(2): 600-610; 1978.

The genome of MC29 virus, a retrovirus that induces a variety of tumors in chickens (ie, myelocytomatosis, kidney and liver carcinomas), and transforms cultures of embryonic avian macrophages and fibroblasts, was characterized, and nucleotide sequences that may encode the oncogenic potential of the virus were identified. MC29 virus can replicate only with the assistance of a related helper virus (MCAV), and the replication defect is apparently due to a deletion in one or more viral genes. The haploid genome of MC29 virus has a mol wt of approx 1.7×10^6 , whereas the MCAV genome has a mol wt of 3.1×10^6 . Although MC29 virus transforms avian fibroblasts in culture, its genome does not contain a gene homologous to the *src* gene responsible for fibroblast transformation by avian sarcoma viruses (ASV's). Radioactive DNA complementary to nucleotide sequences found in the MC29 virus genome (cDNA-MC29), but not in that of MCAV, were prepared. Hybridization data showed that the MC29 virus genome contained approx 1,500 nucleotides not found in MCAV, ASV, or Rous-associated virus 0, an oncogenic virus of chickens. These sequences could encode part or all of the gene(s) responsible for MC29 virus oncogenesis and transformation. The use of cDNA-MC29 will help determine the evolution of MC29 and may assist in identifying its transforming functions and in relating these functions to those of other leukosis-leukemia viruses. (43 refs)

6388 OK 10 Virus, an Avian Retrovirus Resembling the Acute Leukaemia Viruses. (Eng) Oker-Blom, N. (Dept. Virology, Univ. Helsinki and Coll. Veterinary Medicine, Helsinki, Finland); Hortling, L.; Kallio, A.; Nurmiaho, E. L.; Westermarck, H. *J Gen Virol* 30(3): 623-633; 1978.

The isolation and characterization of the OK 10 virus complex, which was derived from a liver tumor in a chicken that had been inoculated iv as an embryo with a field isolate of an avian leukosis virus, are described. Interference assays indicated that this virus complex contained both transforming (OK 10 V) and nontransforming (OK 10 AV) virus, both of subgroup A. OK 10 V, which could not be isolated in vitro without OK 10 AV, induced foci in chick embryo cells under agar overlay, and the cells from these foci formed colonies in soft agar. Injection of virus or infected cells into chicks resulted in acute leukemia but no local tumors. OK 10 AV, which comprised about 99% of the OK 10 complex, did not

induce foci in chick embryo cells, but it caused leukosis in chickens 17 mo after injection. OK 10 stocks showed typical C-type virus particles that had a density of 1.16 g/ml and contained 70S RNA. The latter released type b RNA subunits after heat denaturation. The data indicate that OK 10 virus is related to the subgroup C MH 2 virus or to the acute leukemia viruses of chickens. (33 refs)

6389 Rapid Oncogenesis In Vivo by Chicken Retrovirus OK10. (Eng) Hortling, L. (Dept. Virology, Univ. Helsinki, Haartmaninkatu 3, SF-00290 Helsinki 29, Finland). *Acta Pathol Microbiol Scand (B)* 86(4): 185-192; 1978.

The pathogenesis of OK10 virus infection was studied in 2- to 4-day-old Brown Leghorn chickens injected intraabdominally with 0.5 ml OK10 virus stock (titer: 5×10^4 focus-forming units/ml). The associated virus OK10AV was detected after 1 wk in the bursa of Fabricius, thymus, and liver, but not in spleen and bone marrow. OK10AV was detected in the spleen 3 wk after infection. The transforming virus OK10V was detected only in the bursa of Fabricius 2 wk after infection and in all tissues tested except bone marrow 3 wk after infection. Neutralizing serum antibodies against the OK10 virus complex were detected after 3 wk, when the first tumor was seen in the gut mesentery. After 6 wk, tumors were found in the liver but not in any other organs. When chickens were injected iv with OK10 virus, tumors could also be detected in the liver, kidneys, and testes. The mesenteric tumors were composed of two kinds of cells: clear cells with a large nucleus, prominent nucleoli, and cytoplasmic vacuolation and surrounding lymphocytes. OK10AV was infectious for chickens and induced neutralizing serum antibodies. One of seven chickens infected with OK10AV died of leukosis after 1.5 yr. Continuous cell lines, established from OK10 virus-induced tumors, produced both OK10V and OK10AV viruses and had a blastlike morphology. It is concluded that the OK10 virus complex, composed of a very oncogenic virus OK10V and an associated weakly oncogenic virus OK10AV, may be a good model for studying the mechanism of oncogenesis in vivo and in vitro. (33 refs)

6390 Temperature-sensitive Mutant of Avian Erythroblastosis Virus Suggests a Block of Differentiation as Mechanism of Leukaemogenesis. (Eng) Graf, T. (Institut für Virusforschung, Deutsches Krebsforschungszentrum, im Neuenheimer Feld 280, D-6900 Heidelberg, W. Germany); Ade, N.; Beug, H. *Nature* 275(5680): 496-501; 1978.

Virus-induced leukemic transformation was investigated by isolating a temperature-sensitive (*ts*) mutant of avian erythroblastosis virus (AEV). Erythroblast (EB) colonies were produced by infecting bone marrow cultures with mutagen-treated AEV at 35 C and seeding them into semisolid medium. Cells from individual colonies were propagated at 35 C. Aliquots of these clones were then shifted to 41 C or kept at 35 C and assayed for benzidine-positive (B+) cells. Three clones were *ts* for Hb expression, containing > 70% strongly B+ cells at 41 C and < 10% at 35 C. Clone 34 produced virus (*ts*34 AEV) capable of inducing EB colonies *ts* for Hb expression. *ts*34 AEV (1,000 colony-forming units) was less leukemogenic than the parent virus (10 units) in 8-day-old chicks: there was a decreased incidence of animals that died of leukemia and a delay of onset of disease and death. Most of the leukemic EB's from the peripheral blood of the mutant-infected chicks exhibited *ts* properties. It is suggested that AEV induces a block of differentiation in the erythroid target cells, that this block plays a crucial part in virus-induced leukemogenesis, and that the continuous expression of viral gene product is necessary to maintain the leukemic state of infected cells. (18 refs)

- 78-6391 At Least 104 Nucleotides Are Transposed from the 5' Terminus of the Avian Sarcoma Virus Genome to the 5' Termini of Smaller Viral mRNAs.** (Eng) Cordell, B. (Dept. Biochemistry and Biophysics, Univ. California, San Francisco, CA, 94143); Weiss, S. R.; Varmus, H. E.; Bishop, J. M. *Cell* 15(1): 79-91; 1978.

Based on the previous finding that all three forms of avian sarcoma virus (ASV)-specific cytoplasmic RNA contain a nucleotide sequence that is homologous to a sequence of 101 contiguous nucleotides found at the 5' terminus of the ASV genome, but not within the 3' half of the genome, it was proposed that this nucleotide sequence may be transposed to the 5' termini of viral messenger RNA's (mRNA's) during the genesis of these RNA's. Two strategies were used to substantiate this proposal. First, the three forms of ASV mRNA were isolated by molecular hybridization. Chemical analysis was then used to demonstrate that all three forms shared a capped nucleotide sequence from the 5' terminus of the viral genome, although other portions of the 5' half of the genome were not present in the smaller viral mRNA's. Second, single-stranded DNA complementary to a sequence of 101 nucleotides at the 5' terminus of the ASV genome (cDNA-5') was prepared, and it was shown that all three forms of ASV mRNA could form RNAase-resistant duplexes with the full extent of cDNA-5'. The RNA sequences included in these duplexes were capped and had identical compositions. In contrast, fragments of RNA derived from the 3' half of the ASV genome did not form duplexes with cDNA5'. It is concluded that a sequence of > 100 contiguous nucleotides is transposed from the 5' terminus of the ASV genome to the 5' termini of smaller virus-specific RNA's during the genesis of these RNA's. (53 refs)

- 78-6392 Nucleotide Sequences Related to the Transforming Gene of Avian Sarcoma Virus Are Present in DNA of Uninfected Vertebrates.** (Eng) Spector, H. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Varmus, H. E.; Bishop, J. M. *Proc Natl Acad Sci USA* 75(9): 4102-4106; 1978.

Purified radioactive DNA complementary to the avian sarcoma virus (ASV) transforming gene (cDNA-sarc) was annealed with the DNA of several uninfected species under conditions conducive to pairing of partially matched nucleotide sequences (1.5 M NaCl, 59 C). Denatured DNA's of 10-11-day-old chicken embryos, liver and spleen of a GR mouse, human placental tissue, calf thymus, salmon sperm, sea urchin sperm, *Drosophila* cells grown in culture, *Escherichia coli* cells, and XC cells from a tumor in an ASV-infected chicken were incubated for 96-120 hr with ³H-cDNA-sarc. Duplex formation was measured by hydroxyapatite fractionation. cDNA-sarc formed duplexes with mammalian and fish DNA's (18%-43%), chicken DNA (55%-62%), and XC cells DNA (65%), but only slight annealing occurred with sea urchin DNA and none occurred with *E. coli* or *Drosophila* DNA. Kinetics studies indicated that the nucleotide sequences related to cDNA-sarc in species in which annealing occurred were present as single or only a few copies. The failure of total hybridization in these species was most probably due to stoichiometric limitations imposed by mismatched base pairs and not due to insufficient amounts of cDNA. The degree of base mismatching, as determined by the thermal stability of the duplexes, was approx 3%-4% for chicken DNA and 8%-10% for mammalian or fish DNA. These results indicate that there is a highly conserved set of nucleotide sequences to at least a portion of the ASV sarc gene in the DNA of these vertebrates. (29 refs)

- 78-6393 Specific Restriction of Avian Sarcoma Virus Replication by a Line of Transformed Lymphoid Cells.** (Eng) Neiman, P. E. (Dept. Medicine, Div. Oncology, Univ. Washington, Seattle, WA, 98195); McMillin-Helsel, C.; Cooper, G. M. *Virology* 89(2): 360-371; 1978.

The properties of viral replication on MSB-1 cells, a line of transformed chicken lymphoid cells derived from tumors induced by Marek's disease viruses, were examined. These cells are susceptible to infection by avian leukosis virus (ALV) subgroups A and C, including transformation-defective (non-oncogenic) mutants of avian sarcoma virus (ASV). Various parameters of viral growth revealed that infection of MSB-1 cells by *td* ASV was indistinguishable from infection of chicken embryo fibroblasts (CEF) by *td* ASV. However, the growth of wild-type ASV was restricted in these cells. Further studies, employing Hirt supernatant fractionation, suggested that, following infection of MSB-1 cells with ASV, infectious proviral sequences were synthesized, but the viral DNA did not integrate into host cell DNA in a normal fashion and was lost from the cell. Since replication of *td* ASV does not seem to be restricted in MSB-1 cells, it is concluded that the failure

SV DNA to integrate normally in these cells is due to presence of *src* sequences (genes that confer the ability to transform CEF and other cell types) in the viral genome. (68 refs)

6394 Effect of Glucosamine on Virus Production and Antigen Expression in Avian Sarcoma Virus-transformed Cells. (Eng) Israel, E. (Departement de Microbiologie et d'Immunologie, Universite de Montreal, Montreal, Quebec, Canada); Mandeville, R.; Wainberg, M. *Can J Microbiol* 24(9): 1024-1031; 1978.

The effect of glucosamine (20 mM) on virus production and antigen expression in chicken embryo fibroblast (CEF) cells transformed by avian sarcoma virus was studied. Significant quantities of transforming virus were not synthesized by cells exposed to glucosamine, and glucosamine significantly inhibited viral RNA synthesis and the levels of RNA-dependent RNA polymerase. The inhibition was reduced when glucosamine treatment was carried out in the presence of glucose. Glucosamine treatment also affected antigenic expression in transformed CEF, as measured by an indirect immunofluorescence test, but the degree of inhibition was far less than in a lymphocyte-stimulation assay for the detection of cell-mediated immunity was used. (22 refs)

6395 Synergistic Effect of Tumor Virus Transformation and Tumor Promoter Treatment on the Induction of Plasminogen Activation by Chick Embryo Fibroblasts. (Eng) Goldfarb, R. H. (Dept. Microbiology and Immunology, State Univ. New York, Downstate Medical Center, Brooklyn, NY, 11203); Quigley, J. P. *Cancer Res* 38(12): 4601-4609; 1978.

Studies were carried out to determine whether the tumor promoter phorbol myristate acetate (PMA) could further enhance the protease plasminogen activator (PA) activity in cultures of chick embryo fibroblasts transformed by Rous sarcoma virus (RSVCEF). PMA caused a 12- to 13-fold enhancement of the extracellular PA activity in these cultures, which in the absence of PMA produced at least 50- to 100-fold more PA than did normal chick embryo fibroblasts. The increase in RSVCEF PA activity was first detectable at a PMA concentration of 1 nanogram (ng)/ml, but was maximal when the PMA concentration was between 25 and 100 ng/ml. Increased levels of PA activity in RSVCEF were observed as early as 1-2 hr after PMA treatment. Sodium dodecylsulfate-polyacrylamide gel electrophoresis demonstrated that the PA produced by PMA-treated cultures had a molecular weight identical to that of the PA produced by untreated cultures. Induction by PMA could not be accomplished in cell-free extracts, but required protein synthesis in intact cells. Under serum-free conditions, PMA-treated RSVCEF secreted high levels of PA for 4-6 days and underwent pronounced morphological alterations; large dense colonies of round, refrac-

tile cells formed, and it appeared that at least 80%-90% of the cells in the culture dish were in colonial aggregates. Modified culture conditions and the use of PMA to induce PA allowed the accumulation of large amounts of RSVCEF culture fluid and subsequent purification of the enzyme. The sensitivity of transformed chick embryo fibroblasts to PMA and the generation of enhanced proteolytic activity in the cellular microenvironment may provide a model system to examine the role of both PA in malignant transformation and PMA in tumor promotion. 78-6396 Reversion of Transformed Glycolysis to Normal by Inhibition of Protein Synthesis in Rat Kidney Cells Infected with Temperature-sensitive Mutant of Rous Sarcoma Virus. (Eng) Carroll, R. C. (Dept. Biology, Univ. California at San Diego, La Jolla, CA, 92093); Ash, J. F.; Vogt, P. K.; Singer, S. J. *Proc Natl Acad Sci USA* 75(10): 5015-5019; 1978.

Normal rat kidney cells infected with a temperature-sensitive mutant (LA23) of Rous sarcoma virus exhibit the transformed phenotype when grown at the permissive temperature (33 C) and the normal phenotype when grown at the nonpermissive temperature (39 C). Since the addition of protein synthesis inhibitors to infected cells at the lower temperature causes them to revert to the normal phenotype with respect to morphological and cytoskeletal characteristics, studies were carried out to determine if there is also a reversion in metabolic characteristics. Two sets of experiments, performed at widely separated times, gave qualitatively similar but quantitatively different results. In the first experiments, lactate production was 50%-60% greater in LA23-infected cells at the permissive temperature than in those at the nonpermissive temperature; in the other experiments, the corresponding difference was 80%-100%. In both experiments, all cells showed an increased rate of glycolysis when dinitrophenol was added to the assay, and the control rate/dinitrophenol rate ratio was greater for the transformed phenotype than for normal. In the first experiment, oligomycin inhibited the glycolytic rate of LA23-infected cells at the permissive temperature by more than 70%, but it had no effect in cells grown at the nonpermissive temperature. The glycolytic rate in the transformed cells was unchanged by oligomycin in the second set of experiments, but the drug reproducibly increased the glycolytic rate by about 20% in cells exhibiting the normal phenotype. When transformed cells grown at the 33 C were treated with cycloheximide (15 ng/ml) or abrin (200 ng/ml), the rate of glycolysis without any other additives decreased to normal values. In the first set of experiments, cycloheximide treatment also caused a return to normal of the control rate/dinitrophenol rate ratio and eliminated the oligomycin sensitivity of the rate. Other metabolic changes that might be correlated with transformation were investigated in the second set of experiments: glucose transport, hexokinase activity, and phosphofructokinase activities. The results support the thesis that transformation by the *src* gene of the Rous sarcoma virus is a pleiotropic and

reversible process, such as that involved in a pleiotypic enzymatic modification reaction and its reversal. (31 refs)

- 78-6397 The Expression of Plasminogen Activator in Rous Sarcoma Virus-transformed Cells Is Controlled Both by the Virus and the Cell.** (Eng) Wolf, B. A. (Rockefeller Univ., New York, NY, 10021); Goldberg, A. R. *Virology* 89(2): 570-577; 1978.

The ability of virus produced by clones of Rous sarcoma virus (RSV)-transformed chicken embryo fibroblasts to elevate the level of cellular plasminogen activator (PA) was analyzed by a casein-plaque assay. The genotype of the virus produced by these transformed clones, which exhibit variable low to high levels of PA, was found to be identical to that of the parent virus, regardless of the PA level of the cell in which the virus is replicated. Virus from low PA clones was not defective in its ability to produce transformed cells with increased levels of PA. This virus produced the same spectrum of plaque-forming foci and soft-agar clones as virus from intermediate or high PA clones. These findings lead to the conclusion that the level of PA is cellularly determined. Additional evidence, however, such as the increased expression of PA by superinfection of low activator clones with another strain of RSV, the ability of some RSV strains to elevate PA levels, and the ability of cells infected with some temperature-sensitive *src* mutants to express properties of transformed cells at nonpermissive temperatures, suggests that PA levels are also influenced by the *src* (transforming) gene of RSV. (33 refs)

- 78-6398 Lack of Correlation Between Tumorigenicity and Level of Plasminogen Activator in Fibroblasts Transformed by Rous Sarcoma Virus.** (Eng) Wolf, B. A. (Rockefeller Univ., New York, NY, 10021); Goldberg, A. R. *Proc Natl Acad Sci USA* 75(10): 4967-4971; 1978.

The oncogenicity of chick embryo fibroblast (CEF) clones derived from infection with the replication-defective Bryan strain of Rous sarcoma virus (RSV) was studied to determine whether there is a correlation between tumorigenicity and the level of plasminogen activator (PA) in transformed fibroblasts. CEF clones transformed by B77 and Prague strains of RSV, previously isolated from agar suspension culture, varied in the expression of PA activity, but the tumorigenicity of the transformed cells could not be evaluated with clone cells because B77 and Prague RSV replicate and cause sarcoma in chickens. The range of properties exhibited by the Bryan RSV-derived clones fell within the continuum observed for the B77 and Prague clones. Thus, all clones exhibited an altered (round) morphology, a two- to fivefold greater rate of sugar transport, and a 10^5 - to 10^6 -fold higher efficiency of growth in agar suspension, regardless of the PA level. Five clones, transformed by the Bryan strain and showing low, intermediate, or high PA activity, were tested for tumorigenicity in newborn chicks. The three clones with low

activity exhibited little caseinolysis relative to the clone with the highest activity, even though 3-4 times more cells were assayed. At both cell concentrations tested (500 and 5000 cells/chick), all clones induced tumors at the two sites of injection. Latency periods were similar, regardless of the activator level of the clone injected. Every injected clone induced tumors regardless of its activator activity prior to injection, indicating that tumors exhibiting a spectrum of plasminogen activator activity. No correlations could be made with regard to the level of PA, size of excised tumor, number of cells surviving transplantation, or morphology of explanted tumors. These results confirm previous conclusions that tumorigenicity is not directly related with the level of plasminogen activator. (42 refs)

- 78-6399 Heterogeneity of RNA Synthesized in Lysates of Rous Sarcoma Virus Particles.** (Rus) Petrov, N. N. (N. N. Petrov Oncologic Res. Inst., Leningrad, USSR); Ratovitskii, E. A.; Korobitsyn, L. P.; Kniashuk, P. G.; Seits, I. F. *Dokl Akad Nauk SSSR* 241(3): 714-717; 1978.

The RNA polymerase of lysates of Rous sarcoma virus (RSV) particles was reacted with ^3H - or ^{32}P -labeled ribonucleoside triphosphates, and the product was characterized. The synthesis product was found to be sensitive to RNase A and KOH, but less sensitive to DNase. Electrophoresis in 2.5% polyacrylamide gels revealed two radioactivity peaks at 18S-20S and 4S; there was a shift toward 4S with increasing reaction time, which may indicate the presence of endogenous RNase activity. Synthesis of heteropolynucleotides was observed in the lysates in the presence of all four ribonucleoside triphosphates. Hybridization of the ^3H -labeled product of RNA polymerase reaction, isolated from the RSV lysate with RSV RNA demonstrated that 16% of the ^3H -labeled product has complementary segments with the virion RNA. Thus, the lysates of RSV particles contain an RNA polymerase that catalyzes the synthesis of both homopolynucleotides and heteropolynucleotides, and the synthesis of at least part of the RNA is a matrix reaction, with the matrix being RSV RNA. This fact is of particular interest in light of the generally held view that only RNA-dependent DNA polymerase activity is present in oncornaviruses. (10 refs)

- 78-6400 Complementary Interaction Between Genetic and Immunologic Mechanisms in Determining the Induction of Tumors by Rous Sarcoma Virus on the Chorioallantoic Membrane of the Chick Embryo.** (Eng) Bower, K. (Dept. Botany, Univ. Arkansas at Fayetteville, Fayetteville, AR, 72701); Gyles, N. R. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1645-1658; 1978.

udies were conducted to determine whether the genetic mechanism for regression has any influence on the number of tumors on the chorioallantoic membranes (CAM) of chick embryos and on the regression of tumors induced in young chicks by Rous sarcoma virus (RSV). CAM from 322 chick embryos originating from matings between parents of the rebred Progression and Regression lines were examined. Chick embryos descended from unchallenged regressor (R) parents and from progressor (P) parents were equally susceptible to induction of tumors on CAM by RSV. Chick embryos from immune R parents and those from a parental mating in which only the dam was an immune R demonstrated a marked reduction in tumor counts compared with embryos from P parents. The data suggest that a maternal factor transmitted from the immune hen through the egg interacts with the genotype of the embryo to reduce the number of CAM tumors. Three hundred and forty-four chicks, with parents from the same three breeding groups as those used for the CAM study, were injected in the wing web with RSV at age 1 day, 2 wk, and 4 wk. Day-old chicks descended from immune R parents demonstrated the greatest ability to effect tumor regression compared with chicks from all other mating combinations. This result also demonstrates the importance of an interaction between the maternal factor from immune parents and the genotype of the newly hatched chick in facilitating tumor regression. The influence of the maternal factor diminished sharply at 2 wk of age and was not detectable at 4 wk. (16 refs)

78-6401 Processing of 60,000-Dalton *sarc* Gene Protein Synthesized by Cell-Free Translation. (Eng) Amine, J. (Dept. Biology, Massachusetts Inst. Technology, Cambridge, MA, 02139); Buchanan, J. M. *Proc Natl Acad Sci USA* 75(9): 4399-4403; 1978.

New Zealand White rabbit antiserum directed against the 60,000-dalton (60K) transformation-specific antigen of Schmidt-Ruppin subgroup D Rous sarcoma virus (RD-RSV) immunoprecipitated both the 60K and 25K transformation-specific proteins synthesized by cell-free translation of virion RNA. However, upon incubation of the antiserum with ³⁵S-methionine-labeled protein from RD-RSV-infected cells, a 25K protein and one that was approximately 2K smaller than 60K were immunoprecipitated, which suggests that the primary translation product is processed intracellularly. Peptide mapping of sodium dodecyl sulfate/polyacrylamide gels indicated that the 60K translation product and the 60K cellular protein are closely related structurally. Addition of canine pancreas membrane vesicles to the reticulocyte lysate system during cell-free translation of transforming (*sarc*) gene messenger RNA specifically cleaved a 2K segment from the 60K protein so that it comigrated with the cellular species. Secretory proteins and, probably, at least some integral membrane proteins were synthesized with short hydrophobic signal sequences at their NH₂ terminus. The segment lost from the 60K transformation-specific protein is suggested to be a signal sequence, as the membrane

vesicles processed the 60K protein only during translation and the processed protein was sequestered by the vesicles. It is concluded that the 60K *sarc* protein is synthesized as a precursor with a signal sequence that functions to insert or transport the processed protein into or through cellular membranes. 78-6402 Reversion of Temperature Sensitive Transformation Mutants of Rous Sarcoma Virus and its Effect on the Expression of Tumour Specific Surface Antigen. (Eng) Wyke, J. A. (Imperial Cancer Research Fund, P.O. Box 123, Lincoln's Inn Fields, London WC2A 2PX, England); Kurth, R. *J Gen Virol* 40(3): 701-704; 1978.

To determine whether transformation and the expression of tumor-specific cell-surface antigen (TSSA) are causally related, reversion for TSSA expression was studied in the Rous sarcoma virus mutants *tsLA29* and *tsLA33*, which show a temperature-sensitive (*ts*) expression of TSSA, and their wild-type revertants. Chick embryo fibroblasts infected with *ts* virus showed low TSSA expression at the restrictive temperature (41°C), but cells infected by the two revertants expressed TSSA levels at this temperature comparable to those expressed at the permissive temperature (35°C). The revertants were all wild-type for transformation, as judged by focus formation and sugar transport, and they all showed a wild-type expression of TSSA. The results indicate that it is extremely unlikely that TSSA expression and transformation are unrelated, and they suggest that TSSA is necessary and sufficient for transformation or that TSSA expression is concomitant with but insufficient to account for the appearance of other parameters of transformation. (15 refs)

78-6403 Mechanism of Transfection of Chicken Embryo Fibroblasts by Rous Sarcoma Virus DNA. (Eng) Cooper, G. M. (Sidney Farber Cancer Inst., Boston, MA, 02115); Okenquist, S. *J Virol* 28(1): 45-52; 1978.

The mechanism of transfection of chicken embryo fibroblasts (CEF) by Rous sarcoma virus (RSV) DNA was investigated by assaying DNA-mediated transformation under conditions that restrict secondary virus infection (SVI). CEF that were genetically resistant to virus infection as a result of the absence of receptors for virus penetration were also resistant to transformation by integrated or unintegrated RSV DNA, as assayed by focus formation. Since resistance to RSV infection appears to be expressed at the level of virus penetration, these results indicate that focus formation by RSV DNA required formation of extracellular progeny virus and SVI of sensitive cells. DNA of replication-defective Bryan high-titer RSV was noninfectious, and transformation by DNA of a temperature-sensitive (*ts*) DNA polymerase mutant was *ts*. These results indicate that SVI was necessary for transformation by RSV DNA. Since transformation was also assayed by colony formation in soft agar, the requirement for SVI was not an

artifact of possible difficulties in detecting foci formed only by cell division. Thus, exposure to RSV DNA did not result in genetically stable transformation of the primary DNA-treated recipient cells. The results are consistent with the hypothesis that transfection of CEF by RSV DNA proceeded by transcription of donor DNA, formation of extracellular progeny virus, and SVI of sensitive cells. (30 refs)

- 78-6404 Transfer of Duck Cell DNA Sequences to the Nucleus of 3T3 Cells by Rous Sarcoma Virus.** (Eng) Baxt, W. G. (Biology Dept., Univ. California at San Diego, La Jolla, CA, 92037); Meinkoth, J. L. *Proc Natl Acad Sci USA* 75(9): 4252-4256; 1978.

The ability of a retrovirus [Prague C Rous sarcoma virus (RSV)] to transduce incorporated host polynucleotide sequences into the nucleus of a second unrelated host cell was studied. Upon infection of Peking duck cells by Prague C RSV, polynucleotide sequences complementary to Peking duck cell nuclear DNA were detected in the high-mol-wt RNA from progeny Peking duck cell-passaged RSV (RSV-PD) by RNA-DNA hybridization. When mouse 3T3 cells were subsequently infected by RSV-PD, polynucleotide sequences complementary to Peking duck cell nuclear DNA were detected in the 3T3 cell nuclear DNA by RNA-DNA molecular hybridization. The data introduce the possibility that passage of intact genes or portions of genes between species might occur after evolutionary divergence has taken place. In this manner, the gene composition of organisms could undergo modulation at a rate considerably greater than the one that would result from random mutations alone. (38 refs)

- 78-6405 Isolation and Characterization of a Virus-specific Ribonucleoprotein Complex from Reticuloendotheliosis Virus-transformed Chicken Bone Marrow Cells.** (Eng) Wong, T. C. (Dept. Microbiology, Univ. Texas Health Science Center at Dallas, Southwestern Medical Sch., Dallas, TX, 75235); Kang, C. Y. *J Virol* 28(1): 34-44; 1978.

A ribonucleoprotein (RNP) complex containing endogenous RNA-directed DNA polymerase (RDDP) activity was isolated from the cytoplasm of reticuloendotheliosis virus (REV)-transformed chicken bone marrow cells (BMC) but not from normal BMC. This RNP complex has a density of 1.23 g/cm³ and sediments at 80S-100S in sucrose gradients, properties that indicate that it is distinct from the mature virion. RDDP activity was completely neutralized by anti-REV DNA polymerase antibody but not by anti-avian myeloblastosis virus DNA polymerase antibody. The DNA product from the endogenous RDDP reaction of the RNP complex hybridized to REV RNA but not to avian leukosis virus RNA. The RNA extracted from the RNP hybridized only to REV-specific complementary DNA (cDNA) synthe-

sized from an endogenous DNA polymerase reaction of purified REV. Max hybridization was only 40%; the significance of this apparently low hybridization efficiency is not clear. The size of the RNA in the RNP is 30S-35S, a size equivalent to one subunit of the RNA genome of the virus. No mature genomic RNA was found within the RNP complex. Thus, the formation of mature viral genomic RNA seems to occur after budding, probably during the condensation of nucleoid. (32 refs)

- 78-6406 Protection Against Marek's Disease-derived Tumor Transplants by the Nononcogenic Strain of Marek's Disease Virus.** (Eng) Schat, K. A. (Dept. Avian and Aquatic Animal Medicine, New York State College of Veterinary Medicine, Cornell Univ., Ithaca, NY, 14853); Calnek, B. W. *Infect Immun* 22(1): 225-232; 1978.

The ability of a nononcogenic strain of Marek's disease virus (SB-1) to protect against three Marek's disease-derived tumor transplants was studied in intact, embryonally bursectomized (Bx), or thymectomized (Tx) or cyclophosphamide (CP)-CP/Tx-treated S, N, P, and G-B1 chickens. The chickens were challenged with JMV, a non-virus-producing tumor transplant, or GA/Tr-1 or MDT-198, two virus-producing tumor transplants. Protection was significant when SB-1 (5 × 10⁵ focus-forming units) and JMB (10⁵ viable cells) were administered together, but protection was optimum when challenge was performed 7 days' postvaccination. Protection was abolished by increasing the number of JMV tumor cells to 10⁶ cells or by CP/Tx treatment. Tx, CP, or Bx alone did not ameliorate the immune response. Inactivated SB-1-infected cells (equivalent to 14,300 focus-forming units of live SB-1) were unable to protect against JMV challenge. SB-1 protected against GA/Tr-1, as evidenced by enhanced tumor rejection and the absence of metastases and virus-induced tumors, but not against MDT-198 in intact syngeneic and allogeneic chickens. Protection against MDT-198 was present in vaccinated Bx chickens. It is concluded that protection against JMV is T-cell-dependent and requires the induction of neoantigens not present in the inactivated SB-1 cellular preparation. Several possible explanations for the different responses to GA/Tr-1 and MDT-198 are given. (37 refs)

- 78-6407 70 Nm Particles Detected in Lymphoblastoid Cell Lines Derived from Marek's Disease Tumors.** (Eng) Nii, S. (Dept. Pathology, Res. Inst. Microbial Diseases, Osaka Univ., Yamada-kami, Suita, Osaka, Japan); Yasuda, I.; Ikuta, K. *Biken J* 20(3-4): 151-154; 1977.

The ultrastructure of the 70-nanometer (nm) particles found in two lymphoblastoid cell lines derived from Marek's disease lymphomas (MSB-1 and MOB-1) was determined. Intracellular viral capsids of about 100 nm diameter were found in a few cells from both lines, and about 25% of these capsid-bearing cells also contained the spherical 70-nm particles.

latter were not detected in duck fibroblasts infected with Marek's disease virus, although another aberrant form of the virus could be found in both infected duck embryo fibroblasts and lymphoblastoid cell lines. Most 70-nm particles appeared to consist of an inner spherical structure of high electron density and outer, radially arranged projections of moderate density. It is not certain whether the particles actually have a substructure with rod-shaped projections or whether these projections represent cross-sections of strandlike structures that coil around the inner spherical structure. It is suggested that the 70 nm particle is an aberrant form of Marek's disease virus. (8 refs)

78-6408 Induction of Intracranial Neoplasms by Intracerebral Inoculation of the Bratislava-77 Strain of Avian Sarcoma Virus in Perinatal and Adult F344 Rats: Influence of Age at Inoculation on Tumor Incidence and Morphology and Post-Inoculation Survival. (Eng) Copeand, D. D. (Duke Univ., Durham, NC). *Diss Abstr Int B* (5): 2229; 1978. (no refs)

78-6409 Modulation of Mouse Mammary Tumor Virus Production in the MJY-Alpha Cell Line. (Eng) Magi, M. J. (Dept. Neoplastic Diseases, Mount Sinai Sch. of Medicine, New York, NY, 10029); Blair, P. B.; Lane, M. A. *J Virol* 28(2): 611-623; 1978.

Production of mouse mammary tumor virus (MMTV) virions by the mouse mammary tumor cell line MJY-alpha was shown to be reversibly suppressed by in vivo implantation of the cells into isogenic MMTV-free BALB/c or MMTV-infected BALB/cfC3H mice. This suppression was rapid; the decrease in MMTV particles was observed as early as 7 days after implantation and it remained constant with further in vivo passage of the MJY-alpha tumors. Examination of thin tumor sections by electron microscopy revealed that intracytoplasmic A particles, budding particles, and cell-free MMTV B particles were all affected. However, immunofluorescence assays of the sections demonstrated the presence of MMTV viral antigens in the cells. Cell cultures initiated from the tumors also produced extremely low numbers of virions during the first two passages; after this, the level of MMTV virion synthesis increased and, in later subcultures, was similar to that of the parent cell line. Polypeptide profiles obtained by sodium dodecyl sulfate-polyacrylamide gel electrophoresis of virions purified from these cultures were identical to MMTV. Immunodiffusion demonstrated a cross-reactivity between these virions and MMTV particles obtained from mouse milk. Treatment of MJY-alpha cell cultures with rabbit anti-MMTV antiserum reduced the number of extracellular MMTV virions and altered their electrophoretic polypeptide patterns. Possible reactions for virion particle suppression in vivo are given. (25 refs)

78-6410 Mammary Tumour Virus and Casein Gene Transcription During Mouse Mammary Development. (Eng) Pauley, R. J. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); Rosen, J. M.; Socher, S. H. *Nature* 275(5679): 455-457; 1978.

Mouse mammary tumor virus (MMTV) RNA and casein messenger RNA (mRNA) were quantitated in developing mammary tissue from BALB/c and BALB/cfC3H mice (strains that have a low and high incidence of mammary tumors, respectively) by molecular hybridization with specific complementary DNA (cDNA) probes to MMTV 70S RNA and casein 15S mRNA. The level of MMTV RNA in the mammary tissues was below the limit of detection in virgin and early pregnant BALB/cfC3H mice and was low (0.0014% of the RNA) in mice at midpregnancy. MMTV RNA increased to 0.0125% in the BALB/cfC3H mammary gland in late pregnancy and increased twofold after parturition. The level of MMTV RNA in BALB/c mammary tissues at all the developmental stages assayed was $\leq 0.0005\%$. Casein mRNA was present at 0.0009% of the RNA in the virgin mammary gland, at 0.0066% in early pregnancy, and at 0.365% late in pregnancy. Casein mRNA increased and was maintained at 1% of the RNA during lactation. Following weaning, casein mRNA decreased to 10% of the lactating level, but this level was higher than that observed in the virgin gland. Changes in casein mRNA levels were essentially the same in BALB/c and BALB/cfC3H mice. These studies indicate that the hormonal milieu required for mammary development and lactogenesis enhanced both casein and MMTV expression in the mammary gland of BALB/cfC3H mice. Following weaning, MMTV RNA did not decrease to the same degree as casein mRNA. Therefore, the accumulation of MMTV RNA in BALB/cfC3H mammary glands is dependent upon mammary development and influenced by differentiated mammary function. (28 refs)

78-6411 Hormonal Induction of Mammary Tumor Viruses and Its Implications for Carcinogenesis. (Eng) McGrath, C. M. (Dept. Biology, Michigan Cancer Foundation, 110 E. Warren, Detroit, MI, 48201); Jones, R. F. *Cancer Res* 38(11, part 2): 4112-4125; 1978.

The possibility that hormones and mouse mammary tumor virus (MuMTV) are cocarcinogenic for mammary epithelium was studied in BALB/c and BALB/cfC3H mice. Rates of premalignant (PM) and malignant (M) transformation were compared in cells carrying genetically (BALB/c) or horizontally (BALB/cfC3H) transmitted MuMTV proviral sequences in animals with or without pituitary implants to stimulate hormonal production. The carcinogenesis rate in BALB3cfC3H females was substantially faster than that in BALB3c mice, but the final mammary carcinoma incidence was about the same. Hormonal stimulation promoted PM transformations in noninfected as well as infected females, but the efficiency of PM transformation was substantially greater in infected than in noninfected females. The

rate-limiting step, which infectious MuMTV overcomes, was in PM transformation from the normal state. Integration of new MuMTV sequences in mammary cell DNA was detected by molecular hybridization in cells containing horizontally transmitted MuMTV but not in those germinally infected. MuMTV expression was changed in mammary epithelial cells during hormonal carcinogenesis. Expression of envelope glycopeptides (glycoprotein with a mol wt of 52,000; gp52) was induced, which correlates with amplification of MuMTV RNA sequence content. MuMTV RNA and gp52 were induced by dexamethasone in PM and M cells, but not in normal cells. Both PM and M cells had altered surfaces; the alteration may include membrane incorporation of MuMTV-related determinants of gp52. A hormonal cocarcinogenesis hypothesis is proposed in which expression of germinally transmitted MuMTV genes is the proximal cause of neoplastic transformation. (60 refs)

- 78-6412 Occurrence of Antibody Against Intracytoplasmic A-Particles of Mouse Mammary Tumor Virus in Sera from Breast Cancer Patients.** (Eng) Ogawa, H. (Dept. Surgery, Faculty Medicine, Kyoto Univ., Shogoin-Kawahara-cho, Sakyo-ku, Kyoto 606, Japan); Tanaka, H. *Gann* 69(4): 539-544; 1978.

Antibody to intracytoplasmic A particles (pronucleocapsids of mouse mammary tumor virus) was detected in the sera of 26/43 Japanese breast cancer patients and 4/16 mammary fibroadenoma patients, but in only 4/37 controls. The antibody was detected by indirect immunofluorescence using acetone-fixed smears of A-particle-forming DBA/2 mouse leukemia cells. A-particle clusters fluoresced in discrete granules in the cytoplasm. The presence of the antibody was not correlated with a particular type of tumor histology, blood group, or clinical stage. Twenty of the breast cancer patients were followed after tumor resection: 10/13 antibody-positive patients became negative within 1 yr, and these 10 patients are apparently healthy. Three antibody-negative patients became positive after surgery, but two eventually reverted. Four patients remained negative, three of whom died or suffered a tumor recurrence. The antibody incidence in the breast cancer patients is higher than that detected previously in non-Japanese populations, and a possible ethnic difference is suggested. (28 refs)

- 78-6413 Characterization of a New Virus from *Mus cervicolor* Immunologically Related to the Mouse Mammary Tumor Virus.** (Eng) Schlom, J. (Lab. Viral Carcinogenesis, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014); Hand, P. H.; Teramoto, Y. A.; Callahan, R.; Todaro, G.; Schidlovsky, G. *J Natl Cancer Inst* 61(6): 1509-1519; 1978.

A virus similar to the murine mammary tumor viruses (MuMTV) of the laboratory mouse *Mus musculus* was identi-

fied in the milk of *M. cervicolor popaeus* mice and characterized. The virus was morphologically indistinguishable from B-type MuMTV and was given the designation MC-MTV. Radioimmunoassays for the 52,000-dalton major envelope glycoprotein and the 28,000-dalton major internal protein of MuMTV demonstrated that MC-MTV shared some antigenic determinants with both of these MuMTV proteins. The reactivity was different, however, from that observed with MuMTV tested from *M. musculus*. MC-MTV had a density of 1.16 g/ml in sucrose and a virion-associated DNA polymerase with a divalent cation preference for Mg²⁺ over Mn²⁺. Radioimmunoassay differentiated MC-MTV from the three other viruses previously identified from *M. cervicolor*. MC-MTV is the first virus from another species that is immunologically related to the MuMTV of *M. musculus*. B-type particles similar to MC-MTV were observed in a spontaneous *M. cervicolor popaeus* mammary tumor, and they are being characterized to determine their relationships to the milk-borne MC-MTV particles. (38 refs)

- 78-6414 Detection of Mammary Tumor Virus Antigen in DD/Tbr Strain Mice and the Hybrids.** (Eng) Imai, S. (Second Dept. Pathology, Nara Medical Univ., Nara, Japan). *J Nara Med Assoc* 29(2): 482-489; 1978.

Immunological methods were used to study the mode of transmission of murine mammary tumor virus (MuMTV) antigen expression in DD/Tbr (DD) mice. The incidence of mammary tumors declined in DD mice when they were raised by C57BL/6J mothers; the DD offspring thus raised were designated DDfB. MuMTV antigen was detected by immunodiffusion in the milk of DD mice, BfDD mice (C57BL/6J mice foster-nursed by DD/Tbr mothers), and (female BALB/c x male DD/Tbr)F₁ hybrids, but no antigen was detected in DDfB, BALB/c, C57BL, or (female C57BL/6J x male DDfB)F₁ mice. The transmission of MuMTV through the milk in the DD strain was thus confirmed. Radioimmunoassay revealed MuMTV antigen in the milk of 2/2 DDfB mice and 3/6 (C57BL/6J x DDfB)F₁ mice. The data suggest that DD mice might harbor endogenous MTV. (27 refs)

- 78-6415 Evidence for a Precursor-Product Relationship Between Intracytoplasmic A Particles and Mouse Mammary Tumour Virus Cores.** (Eng) Smith, G. H. (Lab. Molecular Biology, NCI, NIH, Bethesda, MD, 20014). *J Gen Virol* 41(1): 193-200; 1978.

The relationship between intracytoplasmic A particles (CAP) and mouse mammary tumor virus (MMTV) was investigated. CAP were purified from transplantable Leydig cell tumors or from primary mammary tumors in C3H/He mice. Electrophoretic and immunodiffusion techniques detected three MMTV-specific antigenic determinants in CAP (MMTV p27, p14, and p10) and provided evidence that showed that

... sizes and antigenic specificities of these determinants were similar to those of the CAP polypeptides p82, p27, p20-18 and p15-10. The results suggest that CAP possess incompletely processed virion proteins and are intracellular structural precursors to MMTV cores. It is concluded that CAP structural proteins are modified during maturation by protease, i.e., they are reduced to a size comparable to that of the major internal proteins of the virion and that this reaction is determined by the folding of CAP proteins into the morphologically intact A particle. 78-6416 Comparative Susceptibilities of Hybrid Mice to Four Mammary Tumor Viruses from Two Mouse Strains. (Eng) Moore, D. H. (Dept. Microbiology and Immunology, Hahnemann Medical Coll. and Hosp., Philadelphia, PA, 19102); Merryman, C. F.; Maurer, P. H.; Holbrook, J. A. *Cancer Res* 38(11, part 1): 3871-3878; 1978.

The effect of injection of milk containing one of four different strains of murine mammary tumor virus (MuMTV) into several mouse strains and their F₁ hybrids was measured by the recurrence of mammary tumors and the presence of viral antigen in the milk after the third and later litters. BALB/c mice were very susceptible to infection with strain A virus, but C57BL mice and (C57BL x BALB/c)F₁ hybrids were not. Strain Af virus had a low infectivity in all three groups of mice. RIII virus was very infectious in C57BL but less infectious in RIII mice. The susceptibility of (RIII x C57BL)F₁ hybrids was similar to that of C57BL mice. RIII virus was moderately infectious in RIII mice but poorly infectious in both C57BL mice and (RIII x C57BL)F₁ hybrids. However, RIII was highly infectious and produced tumors at an early age in BALB/c mice and (RIII x BALB/c) F₁ hybrids. These results demonstrate the marked influence that the father can exert on the susceptibility of hybrids to a particular virus. There was a good correlation between incidence of infection and incidence of mammary tumors. These experiments point out the complexity of the mouse assay for MuMTV and the erroneous conclusions that may be drawn from a single experiment. (38 refs)

78-6417 Suppression of Chemical (DEN) Carcinogenesis in SWR/J Mice by Goat Antibodies Against Endogenous Murine Leukemia Viruses. (Eng) Pottathil, R. Jackson Lab., Bar Harbor, ME, 04609; Huebner, R. J.; Meisner, H. *Proc Soc Exp Biol Med* 159(1): 65-68; 1978.

The possible involvement of endogenous murine leukemia virus (MuLV) in chemical carcinogenesis in vivo was tested using SWR/J mice treated with diethylnitrosamine (DEN: 0.0 mg/kg ip). The mice were treated with goat anti-radiation leukemia virus (RadLV) and AT124 MuLV IgG before and after DEN treatment, and their effects on the induction and latency of lung tumors were followed. Fifteen of 20 DEN-treated mice immunized with AT124 IgG died from

lung tumors; 50% mortality from lung tumors occurred at 54 wk after treatment. Thirteen of 20 unimmunized controls died with multiple lung tumors; the 50% mortality occurred by the 29th wk. Mice immunized with anti-RadLV IgG survived up to 64 wk after DEN treatment, with 18/20 mice developing lung tumors; 50% mortality occurred at 58 wk. Control mice survived only to 38 wk, with 12/20 developing lung tumors. Immunized mice had larger lung tumors than nonimmunized controls. These data indicate that the survival of antiviral IgG-treated mice was significantly prolonged over that of nonimmunized mice. The antiviral IgG's had apparently very little effect, if any, on tumor growth rate. Although the mechanism of the suppression of chemical carcinogenesis by antiviral IgG's is not clear, the findings indicate that viruses are involved in chemical carcinogenesis. (14 refs)

78-6418 Rapid In Vitro Assay for Thymotropic, Leukemogenic Murine C-Type RNA Viruses. (Eng) Lieberman, M. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA, 94305); Declève, A.; Kaplan, H. S. *Virology* 90(2): 274-278; 1978.

The in vitro quantitation of thymotropic and leukemogenic murine C-type RNA viruses is described. When serial dilutions of murine leukemia viruses (MuLV's) from C57BL/Ka mice were plated on a nonproducer lymphoma cell line derived from a radiation-induced lymphoma of this strain, end-point titers were obtained that correlated well with those obtained by titration methods in vivo. This rapid in vitro assay may be extended to the titration of a variety of MuLV's. (14 refs)

78-6419 Functional Macrophage Cell Lines Transformed by Abelson Leukemia Virus. (Eng) Raschke, W. C. (Developmental Biology Lab., Salk Inst., PO Box 1809, San Diego, CA, 92112); Baird, S.; Ralph, P.; Ninkovic, I. *Cell* 15(1): 261-267; 1978.

Three cloned cell lines that express properties of macrophages were established from murine tumors induced with Abelson leukemia virus (A-MuLV). Two of the three original tumors also yielded lymphocyte cell lines, one typical of the Abelson virus disease and the other a thymic lymphoma. Two of the macrophage lines were tumorigenic when placed in syngeneic BALB/c mice, producing typical A-MuLV lymphocyte neoplasms. All three macrophage lines pinocytosed neutral red, phagocytosed zymosan and latex beads, killed antibody-coated sheep RBC targets, and secreted lysozyme. The co-isolated lymphocyte lines showed none of these properties. Of two macrophage cell lines tested, neither was capable of replacing the adherent cell population required for the induction of in vitro immune responses. Bacterial lipopolysaccharide, an agent that activates normal macrophages, specifically inhibited the growth of the transformed macrophages in culture. The secretion of A-MuLV by two of the

macrophage lines provides conclusive evidence that the Abelson virus is capable of productively infecting the macrophage cell type. The other macrophage line became positive for Abelson virus production after rescue by Moloney leukemia virus. (21 refs)

- 78-6420 Translation of Type C Viral RNAs in *Xenopus laevis* Oocytes: Evidence that the 120,000-Molecular-Weight Polyprotein Expressed in Abelson Leukemia Virus-transformed Cells is Virus Coded.** (Eng) Reynolds, R. K. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); van de Ven, W. J.; Stephenson, J. R. *J Virol* 28(2): 665-670; 1978.

The genomic RNA of two representative mammalian replication-defective transforming viruses, Abelson leukemia virus (AbLV) and woolly monkey sarcoma virus (WMSV), was purified and translated in *Xenopus laevis* oocytes. The major AbLV-specific protein synthesized was a polyprotein (pp) similar in mol wt and immunological properties to a previously described 100,000- to 130,000-dalton pp expressed in AbLV-transformed cells that contained the two amino terminal gag gene proteins p15 and p12. Translation of WMSV RNA resulted in the synthesis of a 55,000-dalton pp consisting of woolly helper virus p30, p15, and p12. The results establish that the nonstructural portion of the 110,000- to 130,000-dalton pp expressed in AbLV-transformed cells is virus-coded. The in vitro translation system may provide a means of testing sera from various sources for antibody directed against their nonstructural components. (20 refs)

- 78-6421 *Fv-1* Regulation of Lymphoma Development and of Thymic, Ecotropic and Xenotropic MuLV Expression in Mice of the AKR/J x RF/J Cross.** (Eng) Mayer, A. (Dept. Genetics and Pathology, Albert Einstein Coll. Medicine, Bronx, NY, 10461); Duran-Reynals, M. L.; Lilly, F. *Cell* 15(2): 429-435; 1978.

The incidence of spontaneous thymic lymphoma in crosses between AKR/J and RF/J mice was studied. AKR mice developed almost a 100% incidence of spontaneous lymphocytic thymic lymphoma. The incidence was much lower in the (AKR x RF)_F hybrids and in about 50% of the (AKR x RF) x AKR backcross mice. This resistance was associated with a reduction in endogenous ecotropic and xenotropic murine leukemia virus (MuLV) expression in the prelymphomatous thymus. The data indicated that the RF mice transmitted an allele at a single locus that resulted in a dominant suppression of lymphoma-inducing, AKR-transmitted genes. This allele appeared to map at the *Fv-1* locus closely linked to the *Gpd-1* locus. The results indicate that the particular *Fv-1* allele of AKR mice provides a permissive genetic background for endogenous ecotropic and xenotropic MuLV expression and that these viral activities may be etiologically involved in the development of spontaneous thymic lymphoma in the mouse. (18 refs)

- 78-6422 Age-dependent Relaxation of Gene Repression: Increase of Endogenous Murine Leukemia Virus-related and Globin-related RNA in Brain and Liver of Mice.** (Eng) Ono, T. (Gerontology Res. Center, Natl. Inst. Aging, Baltimore City Hosps., Baltimore, MD, 21224); Cline, R. G. *Proc Natl Acad Sci USA* 75(9): 4431-4435; 1978.

In order to determine whether a slow loss of differentiation by epigenetic and/or mutational mechanisms could be a common denominator in mammalian aging, any age-dependent expression of specific genes not normally expected to be expressed was investigated. ³H-labeled complementary DNA (cDNA) to the murine leukemia C-type RNA virus (MuLV) genome and globin genes were used as probes to determine the presence of RNA complementary to these genes in RNA extracted from brain and liver of young (6-7 mo), middle-aged (19-20 mo), and old (26-27 mo) C57BL/6J mice. Significant amounts of globin RNA were found in brain nuclei and cytoplasm. There was no age difference in the globin RNA sequences present, but the number of globin RNA molecules increased from 15 in 6-mo-old mice to 34 in 27-mo-old animals for nuclei and from 280 to 500 for cytoplasm. Similar results were found in the liver. RNA complementary to the MuLV cDNA probe was also found in brain and liver nuclei. In contrast to globin, the different RNA sequences increased in brain and liver nuclei from about 45% of the MuLV genome in 6-mo-old animals to 72% in those 27 mo old. The number of MuLV-related RNA molecules remained constant at about 22 and 38 per nuclei for brain and liver, respectively. Derepression of genes of this magnitude could result in a time-dependent increase of virus-related diseases and a general deterioration of the organism. (34 refs)

- 78-6423 Heteroduplex Analysis of the Sequence Relationships Between the RNAs of Mink Cell Focus-inducing and Murine Leukemia Viruses.** (Eng) Chien, Y. H. (Dept. Chemistry, California Inst. Technology, Pasadena, CA, 91125); Verma, I. M.; Shih, T. Y.; Scolnick, E. M.; Davidson, N. *J Virol* 28(1): 352-360; 1978.

Electron microscope heteroduplex analysis was used to study the sequence relationships between AKR ecotropic virus and an AKR-derived mink cell focus-inducing (MCF) isolate (AKR MCF 247), between Moloney murine leukemia virus (M-MLV) and an M-MLV MCF isolate (M-MLV_{MCF}), and between AKR and M-MLV. For the MCF viral RNA of AKR origin and the MCF viral RNA of M-MLV origin, the MCF-specific sequences were located in a region extending from 1.95 to 2.75 kilobases (kb) from the 3' end. Studies of the sequence relationship between AKR and M-MLV showed four major sequence nonhomology regions centered at 1.1, 2.3, 3.3, and 6.8 kb from the 3' end of viral RNA, with lengths of 0.5, 0.6, 0.5, and 0.5 kb, respectively. Further observations suggested that there is some degree of partial sequence mismatch in the entire region from 0.9 to 3.5 kb. However, the AKR and M-MLV sequences immediately adjacent to the 1.95- and 2.75-kb junctions with MCF-specific

ences were relatively similar in AKR and M-MLV. The results suggest that the *env* gene of MLV's maps from 1 to 5 kb from the 3' end of the genomic RNA and that the carboxyl end of the glycoprotein of each MCF strain is similar and identical to that of its ecotropic parent. Thus, the physical distance from heteroduplex structures is consistent with the hypothesis, derived from biological properties and tryptic peptide analysis, that the MCF viruses are recombinant with the *env* gene. (25 refs)

78-6424 Erythropoietin Responsiveness In Vivo of Friend Virus Target Cells for Transformation and Virus Replication. (Eng) Nasrallah, A. G. (Div. Experimental Biology, Baylor Coll. Medicine, Houston, TX, 77030); McGarry, M. P. *Cancer Res* 38(11, part 1): 4-3778; 1978.

In vivo cell transformation by Friend virus (FV) was investigated by a technique that allows selective stimulation of the erythropoietin-responsive cells (ERC) in mice with suppressed multipotential hemopoietic stem cells. DBA/2 mice previously made plethoric by hypertransfusion were administered busulfan (BU: 60 mg/kg intragastrically) in order to depress stem cell populations. On each of the following 3 days, mice received either 8 IU erythropoietin (Ep) or saline injections. Experimental and control mice were injected with equivalent doses of polycythemia-inducing FV. A comparison of the number of target cells transformed in the mice given Ep with those not given Ep provided evidence for the FV as the in vivo compartment in which the target cell for transformation resides. FV-transformed cells were determined by the spleen tumor colony-forming unit assay. Differences in plasma virus titers in Ep-stimulated and non-Ep-stimulated mice revealed that the Ep-responsive cell is predominantly responsible for the production of FV, as measured by focus-forming activity. Mice given saline and FV had very low levels of virus detectable in plasma ($p < 0.01$). Thus, the predominant in vivo target cells for FV replication and tumor colony formation reside within the ERC population. (29 refs)

78-6425 Genetic Resistance in Japanese Wild Mice (*Mus musculus molossinus*) to an NB-tropic Friend Murine Leukemia Virus. (Eng) Odaka, T. (Inst. Medical Science, Univ. Tokyo, P.O. Takanawa, Tokyo 108, Japan); Iwata, H.; Moriwaki, K.; Matsuzawa, A.; Mizuno, M.; Konno, K. *J Natl Cancer Inst* 61(5): 1301-1306; 1978.

Wild mice (*Mus musculus molossinus*; Sk, Hz-VI, Hz-IV, Hz-V, Mol.A, Fu, Te, and Sn) trapped in various areas of Japan were crossed with mice of inbred strains (C57BL/6, C57L, BALB/c, and C57BL/10), and their progeny were infected with NB-tropic Friend murine leukemia virus (F-MuLV: 2.5×10^5 plaque-forming units, ip) at 4 wk of age. Ten days after infection, the spleens were weighed, examined for macroscopic

lesions, and assayed for infectious virus by the XC test. The genotypes of the wild mice were deduced from the responses of the infected progeny. Genetic analysis indicated that 4/8 mice tested had a dominant gene that suppressed virus replication; this gene resembled the *Fv-4'* allele. No mice with the *Fv-2'* allele were found. The gene resembling the *Fv-4'* allele must have an important role in the natural occurrence and propagation of MuLV in wild mice, and it may provide an explanation for the low expression of MuLV in some populations of wild mice. (22 refs)

78-6426 Changes in Cyclic Adenosine 3':5'-Monophosphate Levels During Induction of Differentiation in Murine Erythroleukemia Cells. (Eng) Gazitt, Y. (Dept. Human Genetics and Development, Columbia Univ., Coll. Physicians and Surgeons, New York, NY, 10032); Reuben, R. C.; Deitch, A. D.; Marks, P. A.; Rifkind, R. A. *Cancer Res* 38(11, part 1): 3779-3783; 1978.

Evidence is presented, using synchronized (Syn) and nonsynchronized (NSyn) cultures of Friend virus-infected murine erythroleukemia cells (MELC), that several MELC differentiation-inducing agents induce both an increase in cyclic AMP (cAMP) levels and a transient prolongation of G_1 . The sequential high thymidine (2 mM)-hydroxyurea (0.5 mM) method was used to synchronize the cells. Upon release from cell cycle arrest, the cells go through S in 5 hr, G_2 -M in 1 hr, and G_1 in 3 hr. Syn cells exposed to the inducers hexamethylene bisacetamide, dimethyl sulfoxide, and sodium butyrate progressed through the first Syn cell cycle with the same kinetics as uninduced Syn cells, but remained in G_1 for 6-8 hr. In control cells, the cAMP level was high when cells were at the G_1 -S boundary, fell during S and G_2 -M, and then rose during G_1 . In inducer-treated cells, there was a transient five- to sixfold increase in cAMP during mid-S. In NSyn cultures, an increase in the proportion of cells in G_1 was first noted 6-8 hr after addition of inducer and, depending on the inducer used, could still be detected 10-20 hr later. A transient two- to threefold increase in cAMP occurred 3-6 hr after addition of inducer. Two potent cyclic nucleotide phosphodiesterase inhibitors, 1-methyl-3-isobutylxanthine and RO-20-1724, also increased cAMP, prolonged G_1 , and induced MELC differentiation, but two weaker inhibitors, caffeine (CF) and theophylline (TP), failed to induce differentiation. The fact that TP and CF elevated cAMP and transiently prolonged G_1 but failed to stimulate Hb synthesis suggests that these two effects may not be sufficient to trigger erythroid differentiation or that other effects of these agents prevent differentiation. The magnitude and duration of inducer-mediated prolongation of G_1 did not predict or correlate with the degree of induced differentiation. (35 refs)

78-6427 Mechanism of Genetic Resistance to Friend Virus Leukemia in Mice. V. Relevance of *Fv-3* Gene in the Regulation of In Vivo Immunosuppression. (Eng)

Kumar, V. (Dept. Pathology, Boston Univ. Sch. Medicine, 80 E. Concord St., Boston, MA, 02118); Resnick, P.; Eastcott, J. W.; Bennett, M. *J Natl Cancer Inst* 61(4): 1117-1123; 1978.

An attempt was made to determine if the single autosomal gene *Fv-3*, which regulates susceptibility to immunosuppression by Friend murine leukemia virus (F-MuLV) in vitro, has a similar effect in vivo. Infection of DBA/2, B10.DZ/n, and their progeny F₁ mice with F-MuLV suppressed humoral antibody synthesis in vivo and lymphocyte mitogenesis in vitro. Both these effects of F-MuLV were under host genetic control. In vitro suppression of lymphocyte mitogenesis was regulated by *Fv-3*. Genetic analyses, with the use of the susceptible DBA/2 and resistant B10.D2/n parents and their F₁, intercross, and backcross progeny, indicated that a single autosomal gene dominant for susceptibility regulated the in vivo susceptibility to immunosuppression by F-MuLV. Individual [(DBA/2 x B10.D2)F₁ x B10.D2] mice were typed for susceptibility to F-MuLV-induced suppression of lymphocyte mitogenesis in vitro (an *Fv-3* function) and for susceptibility to immunosuppression by F-MuLV in vivo. This analysis indicated that the same mice that were susceptible or resistant to immunosuppression in vivo were susceptible or resistant to suppression of lymphocyte mitogenesis in vitro. Spearman's rank analysis of the data also indicated that the in vivo and in vitro immunosuppressive effects of F-MuLV were correlated with and not independent of each other. Thus *Fv-3*, which regulates the effect of F-MuLV on lymphocytes in vitro, also appears to regulate the effect of F-MuLV on antibody-forming cells in vivo. (17 refs)

78-6428 Induction of Intracisternal A-Type Particles During Friend Cell Differentiation. (Eng) Ostertag, W. (Max-Planck-Institut für Experimentelle Medizin, 3400 Gottingen, W. Germany); Krieg, C. J.; Cole, T.; Pragnell, I. B.; Swetly, P.; Weimann, B. J.; Dube, S. K. *Exp Cell Res* 116(1): 31-37; 1978.

The regulation of intracisternal A-type particle synthesis during dimethylsulfoxide (Me₂SO)-induced erythroid differentiation was studied in a number of Friend cell lines under conditions which favored or restricted Friend spleen focus-forming virus (FV) production. At least three cell types were derived from the virus positive Friend cell clone F4: Class I lines (V+, A+) produced high levels of infectious FV and low numbers of A-type particles; Class II lines (V+, A++), to which Class I lines could spontaneously and reversibly shift, produced marginal FV and high numbers of A-type particles; and Class III lines (V-, A-) produced neither FV nor A-type particles. Induction of erythroid differentiation in (V+, A++) cells by Me₂SO was paralleled by an increase in C-type, but not A-type, particles. Inhibition of C-type virus production by interferon or azidothymidine was accompanied by a great increase in A-type particle production. A-type particle number was also increased during induction of differentiation in B8 cells, which show an endogenous

defect in Friend virus synthesis (V+, A++). Neither C- nor A-type particles were induced during induction of differentiation in Class III cells, although these cells show a marginal increase in Friend C-type viral RNA levels in the cytoplasm. (V+, A++) cells also showed an increase in Friend virus-related RNA during differentiation. The results suggest that intracisternal A-type particles in Friend cells are related to Friend virus and that the increase in expression of this component is linked to, but is not conditional for, thymopoietic differentiation in Friend cells. (16 refs)

78-6429 Increase in Intracisternal A-Type Particles in Friend Cells During Inhibition of Friend Virus (SFFV) Release by Interferon or Azidothymidine. (Eng) Krieg, C. J. (Max-Planck-Institut für Experimentelle Medizin, D-3400 Gottingen, W. Germany); Ostertag, W.; Clauss, U.; Pragnell, I. B.; Swetly, P.; Roesler, W.; Weimann, B. J. *Exp Cell Res* 116(1): 21-29; 1978.

The effects of interferon and azidothymidine (N₃T), which are known inhibitors of Friend virus synthesis, on the level of intracisternal A-type particles in Friend erythroleukemic (F4-6) cells were studied. Treatment with interferon (10⁶ IU/ml for 4 days) or N₃T (0.25 mM for 35 hr) inhibited spleen focus-forming virus (SFFV) production, reverse transcriptase activity, and the number of C-type particles while increasing the number of intracisternal A-type particles 1- to 20-fold. The A-type particles released from treated cells did not differ in ultrastructure from those released from untreated cells. Interferon treatment of cells, which show an a priori low level of C-type virus synthesis, did not result in an increase in A-type particles. Similarly, the number of A-type particles was not increased by interferon treatment of three C-type virus-releasing cell lines, although C-type virus release was inhibited. Viral RNA levels were not markedly increased during inhibition of C-type virus release in F4-6 cells. The presence and accumulation of A-type particles seems to be related to the production of Friend virus complex (SFFV). (41 refs)

78-6430 Effect of Infection of Mice with Friend Leukemia Complex Viruses on Background Plaque-Forming Cell Production In Vitro. (Eng) Bendinelli, L. (Inst. Microbiology, Univ. Pisa, I-56100 Pisa, Italy); Matteucci, D.; Toniolo, A.; Friedman, H. *Experientia* 34(11): 1161-1162; 1978.

After infection of BALB/c donor mice with Friend leukemia complex viruses and Rowson-Parr virus, the production in vitro of background plaque-forming cells against sheep red blood cells by spleen cells was depressed. (14 refs)

78-6431 Specific Inhibition of XC Syncytia Formation by Anti-MuLV gp69/71 Antibodies. (Eng) G...

brecht, S. (Laboratoire d'Immunologie et de Virologie des
meurs, Inserm U-152, Hopital Cochin, 27 rue du Fau-
arg Saint Jacques, F-75674 Paris Cedex 14, France); Blai-
u, C.; Levy, J. P. *Intervirology* 10(6): 338-344; 1978.

Results of XC syncytia-inhibition tests using ecotropic
murine leukemia virus (MuLV) producer cells and various
viral antisera are presented. The producer cells were:
3-FL cells infected by Gross leukemia virus (GLV);
7BL/6 mouse embryonic fibroblasts infected by Rauscher
leukemia virus (RLV); and (BALB/c x NIH)F₁ hybrid emb-
ryonic fibroblasts infected by Moloney leukemia virus
(MLV). Antisera used included rat antisera against
RLV-induced rat tumors; (W/Fu x B/N)F₁ rat anti-AT124
ecotropic C-type virus; mouse anti-FMR (Friend, Moloney,
Rauscher) sera; monospecific goat antisera against RLV
polypeptides p10, p12, p15, p30, p60, and gp69/71; and nor-
mal sera from uninoculated mice of various strains. When
MLV producer cells were treated with RLV polypeptide an-
tisera prior to coculture with XC cells, antisera against p10,
p12, p15, p30, and p60 were devoid of inhibitory activity,
whereas the two anti-gp69/71 sera were strongly inhibitory,
suggesting that gp69/71 mediates the fusion of mouse pro-
ducer and XC cells. Since this inhibitor is specific for an-
ti-gp69/71, it provides a simple, sensitive, and convenient
assay to type ecotropic C-type viruses and to detect an-
ti-gp69/71 antibodies. The results with normal mouse sera
suggest that older B6 mice and their F₁ hybrids with DBA/2
C3H/He spontaneously produce anti-GLV-gp69/71 an-
tibodies with type-specific activity. (17 refs)

78-6432 **Sequential Changes of T- and B-Cells, Virus An-
tigen Expression and Primary Histologic Tu-
mor Diagnosis in Virus-induced Lymphomagenesis of Mice.**
(Eng) Krueger, G. R. (Immunopathologisches Laboratori-
um, Pathologisches Institut der Universitat Koln, Jo-
seph-Stelzmann-Strasse 9, D-5000 Cologne, W. Germany);
Rauscher, K. M.; Flesch, H. G. *Z Krebsforsch* 92(1): 41-54;
1978.

and B-cell counts, estimation of immunoglobulin (Ig)
receptor fluidity, and expression of virus-coded antigens were
correlated with histological findings during the development
of a virus-induced mouse lymphoma. BALBc mice were in-
oculated at 4 days of age with the strongly oncogenic Moloney
leukemia virus (MLV), the moderately oncogenic (in
BALB/c mice) Gross passage A virus (GLV-A), or the
nononcogenic Gross 3T3 tissue culture virus (GLV-T). Rou-
tine autopsies were done at 2- to 4-wk intervals postinjection
(PI). Several changes were observed in mice with MLV and
GLV-A infection but not in those with GLV-T infection. Ig
receptor fluidity and expression of virus antigen were de-
creased at the initial examination (2 wk PI). There were sig-
nificant decreases in the percentage of T cells 9-12 wk PI,
accompanied by histologic atrophy of the thymus and of
thymus-dependent regions of lymphatic tissues. The first le-
sions histologically suspicious for lymphoma occurred in the

thymus 11-12 wk PI with MLV and 12-20 wk PI with
GLV-A. At 15-20 wk PI with MLV and 20-30 wk PI with
GLV-A, generalized lymphoma was seen. In ultrastructural
studies, there was no specific cell change indicating malignant
transformation of individual cells. There was some indication
of derangement and of a reduction of cytoplasmic microfila-
ments in proliferating lymphoblasts and lymphoma cells. (45

78-6433 **Replication-defective Ecotropic Murine Leu-
kemia Viruses: Detection and Quantitation of
Infectivity Using Helper-dependent XC Plaque Formation.**
(Eng) Rein, A. (Lab. Tumor Virus Genetics, NCI, Bethesda,
MD, 20014); Bassin, R. H. *J Virol* 28(2): 656-660; 1978.

An infectivity assay for a defective variant of Moloney mu-
rine leukemia virus M (MuLV-M) and for other replica-
tion-defective (R-D) ecotropic MuLV's is reported. The vari-
ant was present in a clone of mouse cells (clone 8A) isolated
from a murine sarcoma virus (MSV)-transformed derivative
of mouse 3T3FL cells superinfected with MuLV-M. The as-
say is based on the fact that some isolates of MuLV replicate
well in mouse cells but, unlike nondefective ecotropic
MuLV's, do not induce fusion in XC cells. Particles of R-D
ecotropic MuLV, which do not themselves initiate XC plaque
formation, give rise to XC plaques in cells that are coinfect-
ed with XC-negative, nondefective MuLV. Thus, fusion of XC
cells is a marker by which the defective virus can be specifi-
cally detected in the presence of a nondefective virus. In two
trials, clones 8A and NP-N (a non-plaque-forming variant
of N-tropic MuLV) produced particles that did not form
plaques in the XC test. However, these particles formed XC
plaques when amphotropic MuLV, which is XC-negative,
was added to the assay plates. This phenomenon can be used
as a quantitative infectivity assay for R-D MuLV's. (17 refs)

78-6434 **Ornithine Decarboxylase Activity in Cells
Acutely and Chronically Transformed by Mu-
rine Sarcoma Virus.** (Eng) Kilton, L. J. (NCI-VA Medical
Oncology Unit, NCI, Bethesda, MD, 20014); Gazdar, A. F.
Proc Soc Exp Biol Med 159(1): 142-147; 1978.

Three contact-inhibited or murine sarcoma virus
(MSV)-transformed clones of BALB/3T3 mouse cells were
transformed or supertransformed by MSV or its accompan-
ying nontransforming helper virus (murine leukemia virus,
MuLV), and the relationships between ornithine decarboxy-
lase ODC activity, morphology, virus production, and
growth rates were examined. Clones isolated from these lines
were also studied. All of the virus-infected lines released both
MSV and MuLV. ODC activities could not be correlated with
difference in growth rates or with release of transforming or
nontransforming viruses. The only consistent relationship
was between elevated ODC activity and acute morphological
transformation. With cell passage, ODC levels of acutely

transformed cells returned to baseline levels, perhaps because most acutely transformed cells fail to divide. These findings plus those of a previous study, which indicated that human cytomegalovirus infection of fibroblasts overrides end product repression of ODC by putrescine, suggest that the oncogenic potential of a virus may be related to its ability to interfere with normal regulatory functions of key cellular metabolic enzymes. (16 refs)

78-6435 Enhanced Susceptibility of Virus-Infected Cells to Starch-induced Peritoneal Exudate Cells.

(Eng) Goldman, R. (Dept. Zoology, Univ. Coll. London, Gower St., London, WC1E 6BT, England); Hogg, N. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 97-107; 1977.

Starch-induced peritoneal exudate cells from BALB/c mice were tested for their ability to inhibit 5-¹²⁵I-iodo-2'-deoxyuridine (IUDR) incorporation in normal, virus-infected, or virus-transformed mouse embryo fibroblasts (MEF). Preliminary experiments showed that the PEC abrogated IUDR incorporation in K-BALB cells, and that this cytostatic activity resided in the adherent cell fraction of the PEC, which included macrophages but not T or B lymphocytes. Recently explanted MEF were relatively resistant to PEC-mediated cytostasis. However, secondary MEF transformed by murine sarcoma virus or infected with murine leukemia virus, Sendai virus, or influenza virus were sensitive to PEC cytostasis. Virus-infected or -transformed MEF from four mouse strains (BALB/c, CBA, AKR, C57BL) were affected to a similar degree, indicating that there is no requirement of H-2 compatibility between effector and target cells. These results show that membrane alterations induced by a nontransforming virus infection are sufficient to render cells susceptible to activated, adherent PEC. (26 refs)

78-6436 Structural Markers on Core Protein p30 of Murine Leukemia Virus: Functional Correlation with Fv-1 Tropism. (Eng) Gautsch, J. W. (Res. Inst. Scripps Clinic, 10666 N. Torrey Pines Road, La Jolla, CA, 92037); Elder, J. H.; Schindler, J.; Jensen, F. C.; Lerner, R. A. *Proc Natl Acad Sci USA* 75(9): 4170-4174; 1978.

The primary structure of the major core protein, p30, of murine leukemia virus (MuLV) was studied in over 50 virus isolates by a simplified method of in situ radioiodination and two-dimensional peptide mapping. Although all MuLV p30's displayed a close structural similarity, minor differences in the peptide profiles did occur, and they were reproducible and served as excellent markers for certain MuLV strains. A loss of peptide spots 1 and/or 2 in the peptide map was noted only in Friend, Moloney, and Rauscher leukemia viruses, and not endogenous MuLV. Peptide 12, which varied

in its relative position more than any other peptide in the maps, exhibited one of four primary positions, and was to be functionally associated with Fv-1 tropism. On this basis a virus could be classified as N-tropic, B-tropic, xenotropic and/or from a wild mouse. Although phenotypically identical, two BALB/c B-tropic isolates, WN1802B and B could be genotypically distinguished, as could two different BALB/c xenotropic viruses, B-228 and Mk-137MC. The clone of Moloney murine sarcoma virus was seen to possess extra marker peptides derived from the COOH end of that could be sarcoma-associated. (38 refs)

78-6437 Further Evidence for Deletion of Envelope Glycoprotein (gp69/71) Sequences in Formation of Moloney-Murine Sarcoma Virus. (Eng) Peebles, P. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD); Straube, M.; August, J. T. *J Gen Virol* 40(3): 503-510; 1978.

The S+L-strain of Moloney murine sarcoma virus (M-MuSV) was nonproductively cloned in S+L-mouse, dog, mink, and human cells, and expression of the Moloney murine leukemia virus (M-MuLV) 30,000-mol wt core protein (p30) and envelope glycoprotein (gp69/71) was studied by radioimmunoassay. In all cases, the p30 determinant, which has been demonstrated to be part of a larger p60 protein precursor, remained associated with the MSV genome. However, heterologous host S+L- cell line showed evidence for M-MuLV gp69/71. These data support previous biological data and suggest that the gp69/71 gene was deleted in the formation of this MSV genome. The S+L- dog cells released large amounts of a soluble p30 antigenic determinant in their culture supernatant fluids in the absence of detectable virus particle production and under optimal conditions for cell viability. This is the first example of the in vitro release of a major structural core virus protein in soluble form in the absence of virus particle production. (31 refs)

78-6438 Biochemical Studies on RNA Tumor Virus Replication and its Transmission in B16 Murine Melanoma. (Eng) Hehlmann, R. (Med. Poliklinik, Universität München, Munich, W. Germany); Erfle, V. *Int J Cancer* 22(5): 630-638; 1978.

The RNA tumor virus information of the B16 mouse melanoma system and its transmission were studied biochemically. Density-fractionated B16 melanomas contained particles possessing a 70S RNA associated with a reverse transcriptase. The particles had a density of 1.14-1.18 g/cm³ along 25%-55% sucrose gradient. The ³H-complementary DNA synthesized by these particles hybridized back to its template RNA. The B16 particle RNA showed considerable homology with the RNA's of the murine leukemia-sarcoma virus AKR-MuLV, Kirsten-MuSV, and Rauscher-MuLV and some degree of homology to the RNA's from simian sarcoma virus and RD-114 viruses. In addition, the B16 DNA con-

med particle-related sequences not present in the DNA of normal C57BL mice. (30 refs)

78-6439 Chemical Determination of the m1 Moloney Sarcoma Virus pP60gag Gene Order: Evidence for Unique Peptides in the Carboxy Terminus of the Polyprotein. (Eng) Oskarsson, M. K. (Lab. DNA Tumor Viruses, NCI, Bethesda, MD, 20014); Elder, J. H.; Gautsch, J. W.; Turner, R. A.; Vande Woude, G. F. *Proc Natl Acad Sci USA* 10(10): 4694-4698; 1978.

The gene order of the m1 isolate of Moloney sarcoma virus (MSV) specific polyprotein pP60gag (P60) was determined by direct chemical analysis. P60 was cleaved with cyanogen bromide (CNBr) into eight partial and complete fragments ranging from 10,000 daltons to 58,000 daltons. Peptide maps of these fragments were compared with maps of p15, p12, and three CNBr fragments of p30. The polarity of p15 and p12 in a CNBr fragment of P60 was determined by carboxypeptidase A digestion; the CNBr fragments of p30 were ordered by aminopeptidase digestion. The linear arrangement of P60 CNBr fragments gave the gene order of H_2 -p15-p12-p30-COOH. This linear arrangement of CNBr fragments should facilitate primary amino acid sequence analysis of the polyprotein. In addition, as demonstrated with MSV P70, this map should serve as a useful basis for comparison to other MSV or Moloney murine leukemia virus (MLV) gag polyproteins when the latter are available in sufficient quantities. The m3 isolate of MSV expressed a P70 gag protein. Peptide maps of 48,000-dalton CNBr fragments of m3 P70 and m1 P60 were similar, which suggested that these polyproteins were similar through the NH_2 -terminal two-thirds of p30. However, the presence of peptides unique to the 10,500-dalton COOH-terminal fragment of m1MSV P60, ie, peptides absent in the p30 of either m3MSV or MLV, suggested that the gag gene deletion in the m1 isolate begins at the p30 reading frame. 78-6440 Feline Sarcoma Virus In Vitro Infection of Human Cells. Influence of Chemical Carcinogens on Focus Formation. (Eng) Blakeslee, J. R. (Dept. Veterinary Pathobiology, Coll. Veterinary Medicine, Ohio State Univ., 25 Coffey Road, Columbus, OH, 43210); Milo, G. E. *Chem Biol Interact* 23(1): 1-11; 1978.

The effects of benzo(a)pyrene (BP), aflatoxin B₁ (AFB₁), and 2-acetoxy-2-fluorenylacemide (A-AAF) on Synder-Theil feline sarcoma virus-induced focus formation was studied using normal human foreskin fibroblasts (D550). Focus formation was inhibited by 27% to 60% in cells treated with 1.0-15.0 μ g/ml 24 hr before virus infection, by 65% to 87% in cells treated 6 hr before infection, by 59% to 87% in cells treated 2 hr before infection, and by 31% to 42% in cells treated after infection. A 43% inhibition occurred in cells treated with A-AAF (1.0 μ g/ml) 6 hr before infection,

70% in cells treated 2 hr after infection, and 55% in cells treated 24 hr after virus adsorption. AFB₁ inhibited focus formation by 39% in cells treated with 1.0 μ g/ml 6 hr before virus infection and by 46% to 59% in cells treated with 0.1 μ g/ml after infection. Focus formation was not significantly altered by treatment before or after infection with pyrene (10 μ g/ml) or 0.1 μ g/ml A-AAF or by treatment before infection with 0.1 μ g/ml AFB₁. Focus formation was not inhibited in cells treated with BP (15 μ g/ml) or AFB₁ (0.1 μ g/ml) 48 to 96 hr postinfection. Virus-directed RNA-dependent DNA polymerase activity was not reduced in cells showing significant inhibition of focus formation, and no infectious virus was detected in either treated or untreated virus-infected cells. The data indicate that the inhibitory effect on focus formation is chemically mediated, whereas the inhibition of virus synthesis is not. (14 refs)

78-6441 Endogenous Feline Oncoviruses: Genome Expression of RD-114 and Feline Leukemia Virus in Normal and Abnormal Differentiation of the Domestic Cat (*Felis catus*). (Eng) Niman, H. L. (Univ. Southern California, Los Angeles, CA, 90007). *Diss Abstr Int B* 39(5): 2131; 1978. (no refs)

78-6442 Feline Leukemia Virus Envelope Glycoprotein Vaccine: Preparation and Evaluation of Immunizing Potency in Guinea Pig and Cat. (Eng) Salerno, R. A. (Div. Virus and Cell Biology Res., Merck Inst. Therapeutic Res., West Point, PA, 19486); Lehman, E. D.; Larson, V. M.; Hilleman, M. R. *J Natl Cancer Inst* 61(6): 1487-1493; 1978.

Envelope glycoprotein (gp) of feline leukemia virus (FeLV), strain FeLV-1, was extracted with 2% Triton X-100 and 0.43 M sodium chloride in 10 mM Tris (pH 7.5) and purified by ion-exchange chromatography on phosphocellulose. Purified FeLV envelope gp75 (mol wt 75,000 daltons) induced antibodies of high titer in goats. These antibodies specifically neutralized FeLV, precipitated radiolabeled FeLV envelope gp75, and lysed FL74 cells. Administration of 20 μ g gp75 to guinea pigs in alum or adjuvant 65 induced neutralizing antibody [geometric mean titer (GMT), 8-25], radioimmune precipitating antibody (GMT, 1,382-6,450), and cytotoxic antibody (titer, ≥ 2) in all animals. Aqueous gp75 vaccine induced neutralizing antibody (GMT, < 4) in only 50% of the guinea pigs. Specific-pathogen-free cats immunized with 40 μ g gp75 in alum or Freund's adjuvant developed radioimmune antibody with GMT's of 127-207 (100% seroconversion, SC), but little or no neutralizing antibody (22%-38% SC; GMT, < 2) or cytotoxic antibody (0%-44% SC) developed. These findings indicate that oncovirus subunit vaccines will require highly effective immunologic adjuvants to enhance the immunogenicity of the antigen in the homologous host. (36 refs)

78-6443 Feline Oncornavirus-associated Cell Membrane Antigen. (Eng) Essex, M. (Dept. Microbiology, Harvard Univ. Sch. Public Health, Boston, MA, 02115); de Noronha, F.; Oroszlan, S.; Hardy, W. D. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1401-1414; 1978.

The object of this study was twofold: (1) to determine if feline leukemia virus (FeLV) proteins gp70, p27, and p15 were detectable on the surface of feline leukemia or lymphoma cells (including cell culture lines and freshly biopsied tumor cells) and (2) to determine if feline oncornavirus-associated membrane antigen (FOCMA) activity (found naturally in healthy virus-exposed cats) could be adsorbed or removed with either pure intact or fractionated FeLV. Monospecific goat or rabbit antisera to gp70, p27, and p15 indicated that these antigens are present on FOCMA-positive cells that produce FeLV, including two cultured lymphoblastoid lines and biopsied cells from cats with naturally occurring leukemia and lymphoma. However, the antibody activity from these monospecific antisera was readily removed by adsorption with either pure gp70, p27, or p15 or whole disrupted FeLV. In contrast, similar treatment of feline sera containing high titers of FOCMA antibody did not remove antibody activity directed to the surface of virus-producer tumor cells. It is concluded that FOCMA contain antigenic determinants that are not shared with the major virus structural proteins. (43 refs)

78-6444 Characterization of a Feline Sarcoma Virus-coded Antigen (FOCMA-S) by Radioimmunoassay. (Eng) Sherr, C. J. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Todaro, G. J.; Sliski, A.; Essex, M. *Proc Natl Acad Sci USA* 75(9): 4489-4493; 1978.

The previously detected expression of a feline oncornavirus-associated cell membrane antigen (FOCMA) on feline sarcoma virus (FeSV)-transformed rat and mink nonproducer cells (FOCMA-S) provided evidence that this antigen is encoded by a feline C-type viral gene. The presence of FOCMA-S in FeSV pseudotype particles facilitated the development of a radioimmunoassay (RIA) for an FeSV gene product that uses rabbit antiserum and protein derived from viral particles produced by nonfeline (mink, rat) cell. Thus, it was possible to assay for FOCMA-S with reagents generated completely outside of the feline system. Although the polypeptide (p85) detected in pseudotype virions contained p15 and p12 antigenic determinants, antibodies to these could be adsorbed with purified feline leukemia virus (FeLV) proteins. Hence, the RIA for FOCMA-S did not detect the major viral structural protein antigens found in p85. The adsorbed rabbit antiserum bound to antigenic determinants also present in

p85 and reacted specifically in immunofluorescence tests of rat cells transformed by FeSV and with FOCMA-positive lymphoid tumor cells. Competition assays detected FOCMA-S in pseudotype C-type viruses rescued from FeSV-transformed mink and rat cells, but not in heterologous C-type helper viruses or in FeLV. A cross-reactive antigen was also detected in pseudotype of Kirsten sarcoma virus. This quantitative assay could also be used to purify viral antigens from transformed cells and to characterize these potential 'transforming proteins.' (26 refs)

78-6445 Demonstration of Two Distinct Classes of Bovine Papilloma Virus. (Eng) Lancaster, W. (Div. Otolaryngology, Case Western Reserve Univ., Cleveland, OH, 44106); Olson, C. *Virology* 89(2): 372-379; 1978.

The purpose of this study was to determine if different classes of bovine papilloma virus (BPV) exist. Virus DNA was isolated and purified from 10 naturally occurring cases of bovine fibropapillomatosis and hybridized to labeled BPV DNA. Results indicate that two distinct classes of BPV can be distinguished based on the extent of hybridization. Saturating hybridization showed that the two virus classes shared 52%-58% of their polynucleotide sequences. DNA-DNA reassociating kinetics revealed that the two virus classes shared a common base pairs along 45% of the genome. The viruses differed in their ability to hemagglutinate mouse RBCs, they were antigenically cross-reactive but not identical in complement fixation and hemagglutination inhibition. Although many of the structural proteins of the two virus classes seemed to have similar electrophoretic mobilities on sodium dodecyl sulfate-polyacrylamide gels, a more detailed analysis will be required to detect minor differences in molecular weight. There were no differences between the viruses with respect to location or morphology of papillomas or to a preference for a given bovine breed. (23 refs)

78-6446 Common Membrane Neoantigens on Bovine Papilloma Virus-induced Fibroma Cells from Cattle and Horses. (Eng) Barthold, S. W. (Section Comparative Medicine, Yale Univ. Sch. Medicine, New Haven, CT 06510); Olson, C. *Am J Vet Res* 39(10): 1643-1645; 1978.

Bovine papilloma virus (BPV)-induced fibroblastic tumors in cattle, horses, and hamsters were studied by indirect immunofluorescence in order to identify common antigens. Sixteen calves <2 wk old and six adult ponies were inoculated with 0.1-0.2 ml of 20%-30% BPV homogenate in multiple sites. Serum was collected at inoculation and at various specified times afterward. Nine outbred Syrian hamsters were inoculated sc with 0.2 ml of homogenate, and a tumor from one of these hamsters was transplanted sc into 13 other hamsters. Four calves developed fibromas, three fibropapillomas. Two ponies developed fibromas. Seven of nine hamsters developed fibrosarcomas, and all those with transplanted tumor de-

ed large sarcomas. Specific membrane IF occurred on boe and equine tumor explant cells, but not on normal derl cells, if reacted against homologous or heterologous sera. cept for two bovine sera, the reactions of bovine sera to ine tumor cells and equine tumor cells were similar. The ction pattern of equine sera was similar, but seemed to be dified by tumor size of the serum source. The reaction ild be blocked in both species by homologous, but not erologous, sera. Sera from tumor-bearing hamsters had no ectable reactivity to cell membranes of hamster, bovine, equine cells. Internal neoantigens were not found in any the acetone-fixed tumor cells, using sera from the three cies. Both tumor and normal cells were found free of BPV igen by direct IF. (30 refs)

6447 **Replication of Nondefective Parvoviruses: Lack of a Virion-associated DNA Polymerase.** (Eng) tchard, C. (Dept. Biology, Virginia Polytechnic Inst., icksburg, VA, 24061); Patton, J. T.; Bates, R. C.; Stout, R. *J Virol* 28(1): 20-27; 1978.

ur nondefective parvoviruses, bovine parvovirus (BPV), l, LuIII, and Kilham rat virus (KRV), were examined for ion-associated DNA polymerase activity. Virions were rified from neuraminidase-treated infected cell lysates by pycnic centrifugation in CsCl or from infected cell materi- by CaCl₂ precipitation and centrifugation through sucrose o CsCl. BPV and KRV preparations obtained by the for- procedure contained DNA polymerase activity but were e free of contaminating cellular proteins. In both cases, the latest amount of residual enzyme activity consisted of NA polymerase β . The latter method produced viral prepa- tions free of contaminating cellular proteins, and no DNA ymerase activity was detected in any of the four viruses. rruption of infectious virions obtained by the second meth- with ionic and nonionic detergents and sonic treatment d not result in the detection of a DNA polymerase. The ological activity and purity of each of the viruses were de- mined by hemagglutination and infectivity assays, poly- /amide gel electrophoresis, and electron microscopy. In ch case, the virions banding at a density of 1.39-1.41 g/cm³ CsCl were infectious and contained only the virion struc- al proteins. DNA polymerase activity was not detected in y of the purified virus preparations. It is concluded that RV, BPV, H-1, and LuIII do not contain an essential vin- ion-associated DNA polymerase required for productive in- tion. (25 refs)

-6448 **Viral DNA Synthesis in Cells Infected with Temperature-sensitive Mutants of Herpes Sim- plex Virus Type 1.** (Eng) Bone, D. R. (Tumor Virology Lab., lk Inst. Biological Studies, San Diego, CA, 92112); Brown, ; Crombie, I.; Francke, B. *J Virol* 28(1): 14-19; 1978.

temperature-sensitive (*ts*) mutants of herpes simplex virus

type 1 (HSV-1) representing eight DNA-negative (DNA-) complementation groups were characterized in tempera- ture-shift experiments. Viral DNA synthesis was measured in mutant-infected baby hamster kidney (BHK-21) cells after (a) shift-up to the nonpermissive temperature (39 C) to deter- mine whether synthesis continued or was inhibited and (b) shift-down to the permissive temperature (32 C) in the pres- ence and absence of inhibitors of protein and RNA synthesis. The mutants could be grouped into three categories based on the results of these experiments. (1) After shift-up, viral DNA synthesis was inhibited in cells infected with *tsB*, *tsH*, and *tsJ*, indicating that the B, H, and J proteins are continuously required for this process. Cells infected with *tsB* and *tsH* syn- thesized viral DNA after shift-down in the absence of de novo RNA and protein synthesis; *tsJ*-infected cells did not synthe- size viral DNA in the absence of protein synthesis. (2) Viral DNA synthesis continued after shift-up in cells infected with *tsD* and *tsK* but not after shift-down in the absence of RNA and protein synthesis, suggesting that these mutants are de- fective in early regulatory functions. (3) Cells infected with *tsL*, *tsS*, and *tsU* synthesized viral DNA after shift-up and after shift-down in the absence of RNA and protein synthesis. The functions of the L, S, and U proteins were not clarified. (11 refs)

78-6449 **Frequency of Anti-AG-4 Antibody in Patients with Uterine Cervical Cancer and Controls.** (Eng) Kawana, T. (Dept. Obstetrics and Gynecology, Facul- ty Medicine, Univ. Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo 113, Japan); Sakamoto, S.; Kasamatsu, T.; Aurelian, L. *Gann* 69(4): 589-591; 1978.

The association of herpesvirus type 2 (HSV-2) with cervical cancer was investigated by determining the prevalence of an- tibody to an early antigen (Ag-4, an antigen that is induced in Hep-2 cells by HSV-2 4 hr after infection) in 33 Japanese cancer patients and 30 age-matched controls. A microquan- titative complement fixation assay detected antibody Ag-4 in 17/33 patients and 5/30 controls. There was a tendency for antibody prevalence to increase with clinical stage: 43% at Stage I, 63% at Stage II, and 75% at Stage III. A neutraliza- tion kinetics assay showed that 11/15 anti-Ag-4-positive sera contained neutralizing antibody to HSV-2, as did 11/16 anti-Ag-4-negative sera. Eleven of 22 HSV-2-positive sera were also Ag-4-positive, which indicates that there is no correla- tion between the prevalence of Ag-4 antibody and that of HSV-2 neutralizing antibody. Thus, Ag-4 differs from viral antigens involved in neutralization. These results, similar to those of several US studies, suggest that HSV-2 is associated with cervical cancer and appears to reflect tumor progression. There are two possible explanations for the observation that only 17/34 patients were Ag-4-positive: antibody levels in the negative patients were too low for detection or the negative patients were not previously exposed to HSV-2. The latter explanation suggests that HSV-1 may be associated with cer- vical cancer in Ag-4-negative patients. (10 refs)

- 78-6450 Selective Stimulation and Differentiation of Early Antigens in Lymphoblastoid Cell Lines Producing Epstein-Barr-Like Viruses.** (Eng) Neubauer, R. H. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Rabin, H.; Brown, A. M. *J Gen Virol* 41(2): 295-301; 1978.

The early antigens (EA) of Epstein-Barr virus (EBV), *herpesvirus papio*, *herpesvirus pongu*, and *herpesvirus pan* were examined using a procedure that combines antigen stimulation with inhibition of late virus functions and results in the selective stimulation of EA. Treatments combining 5-iodo-2'-deoxyuridine and phosphonoacetic acid (PAA) resulted in the selective stimulation of EA in lymphoblastoid cell lines that produce EBV-related viruses. The marked increase in the frequency of EA-positive cells in the relative absence of virus capsid antigens permitted the comparison of EA in related viruses. The EA's of the four viruses were distinguishable, with the greatest differences being between EBV and *h. papio*. The differences were indicated by the ability to select sera that had positive reactivity only with the homologous antigen and by differences in homologous and heterologous titers in certain cross-reacting sera. These differences were also demonstrable for both the restricted and diffuse components of EA, and, they suggest that EBV-related viruses can be distinguished by their early antigens as well as by comparisons of virus-specific nuclear antigens and DNA hybridization techniques. (11 refs)

- 78-6451 Chloroquine Enhances Epstein-Barr Virus Expression.** (Eng) Karmali, R. A. (Dept. Pathology, Sch. Medicine, East Carolina Univ., Greenville, NC, 27884); Horrobin, D. F.; Menezes, J.; Patel, P.; Musto, J. *Nature* 275(5679): 444-445; 1978.

The effect of chloroquine (CQ), an antimalarial agent, on the expression of Epstein-Barr virus (EBV) antigens was studied in the Raji cell line, which is EBV-induced nuclear antigen (EBNA)-positive, early antigen (EA)-negative, and virus capsid antigen (VCA)-negative. The cells were superinfected with the P3HR-1 strain of EBV for the induction of EA and VCA. CQ was added to the infected cells, and the cultures were incubated for 48 hr. Indirect immunofluorescence showed that 6.5% of the infected cells were EA-positive. Following treatment with 0.1, 1.0, or 5.0 $\mu\text{g}/\text{ml}$ CQ, however, 19%, 16.8%, and 18.3% of the cells were EA-positive, respectively. (Plasma concentrations of CQ in humans during malaria chemotherapy are 0.16-0.53 $\mu\text{g}/\text{ml}$.) There was no difference in VCA-positive cells in the presence of CQ. These results suggest that CQ may be acting either directly on the exogenous EBV genome or indirectly, by activating cellular mechanisms essential for its expression. Therefore, CQ may play an important part in the development of African Burkitt's lymphoma by enhancing EBV expression. (26 refs)

- 78-6452 Longitudinal Study of Epstein-Barr Virus Antibody Titers and Excretion in Pediatric Patients**

with Hodgkin's Disease. (Eng) Lange, B. (Div. Oncology, Children's Hosp. Philadelphia, Philadelphia, PA, 19104); Beter, A.; Hewetson, J.; Henle, W. *Int J Cancer* 22: 521-527; 1978.

An attempt was made to provide evidence of the latent acter of Epstein-Barr virus (EBV) infection by monitoring children with Hodgkin's disease (HD) and a history of infection for changes in the titers and spectra of antibody to EBV-determined antigens, excretion of the virus in oropharynx, EVB-carrying lymphoid cells in the peripheral blood, and clinical parameters signifying a reactivation of latent viral condition. Although the incidence and geometric mean titers of IgG antibodies to viral capsid antigen (VCA) in the HD patients were similar at diagnosis to those of controls, the anti-VCA titers rose significantly above controls during and after therapy and remained elevated throughout the 7 yr of observation. At no time were heterophil VCA-specific IgM antibodies detected. Antibodies to EBV-induced early antigens were much more common (10% vs 9%) and antibody levels to EBV-associated nuclear antigen were significantly lower in HD patients than in controls. No specific clinical alterations were correlated with the elevated antibody titers or the observed increase in EBV excretion. Although a reactivation of EBV infection by the immunosuppressive effects of HD or its therapy is presently the best explanation of these results, direct evidence has yet to be provided. (38 refs)

- 78-6453 Isolation of a Herpesvirus-specific DNA Polymerase from Tissues of an American Patient with Burkitt Lymphoma.** (Eng) Allaudeen, H. S. (Dept. Pharmacology, Yale Univ. Sch. Medicine, New Haven, CT 06510); Bertino, J. R. *Proc Natl Acad Sci USA* 75: 4504-4508; 1978.

A DNA polymerase (Pase) isolated from a 27-yr-old white American man with Burkitt's lymphoma (BL) showed specific properties of herpes simplex virus (HSV)-induced DNA polymerase and the Epstein-Barr virus (EBV) DNA Pase of Burkitt's lymphoma in culture. The enzyme was partially purified from a crude extract and separated from the cellular DNA Pases. The DNA Pase, which represented 27%-30% of the total cellular DNA activity, differed from the cellular DNA Pases. Its molecular wt was determined to be 90,000 by velocity sedimentation. The activity of the enzyme increased three to four times in the presence of high salt concentrations (100 mM), similar to HPV DNA Pase. This enzyme further resembled HSV DNA Pase in its primer template preference, high monovalent cation requirement for activity, and sensitivity to phosphonoacetate inhibition. N-Ethylmaleimide had no effect on its activity. HSV DNA Pase antiserum inhibited the activity of BL DNA Pase, whereas antibody to HeLa cell DNA Pase α or to DNA Pase γ from human lymphoblast cells did not. Although the patient's serum contained a high EBV titer, addition of the serum to the assay mixture did not have any effect on the activity of BL DNA Pase. Spleen and liver

did not contain HSV DNA. Detection of the HSV DNA in BL tissue provides additional evidence for the association of EBV with this malignancy. (17 refs)

78-6454 Induction of Nuclear Antigen (EBNA) Synthesis Without Transformation in Human Cord Lymphocytes by P3HR-1 Strain of Epstein-Barr Virus. (Eng) Yamamoto, N. (Dept. Microbiology, Kumamoto Univ. Medical Sch., Kumamoto, 860, Japan); Hinuma, Y. *Immunology* 89(2): 623-626; 1978.

The transforming potential of the P3HR-1 strain of Epstein-Barr virus (EBV) was analyzed by clonal transformation in soft agar, and EBV-determined nuclear antigen (EBNA) induction by this virus was investigated in primary cultures of normal umbilical cord lymphocytes. The B95-8 strain of EBV was used as a positive control. Experiments with six cord cell preparations from different neonates showed that all nine preparations of P3HR-1 virus gave negative transformation results, but all cell preparations infected with B95-8 virus were transformed. In addition, EBNA-positive cells were present in all P3HR-1-infected cultures. EBNA synthesis without transformation was confirmed through colcemid treatment of P3HR-1-infected cord cells. No labeled cells were found upon autoradiographic examination of cells infected with P3HR-1 and exposed to ³H-thymidine at several intervals after infection. It is concluded that EBNA synthesis does not correlate with transformation and that DNA synthesis is not necessary for EBNA induction. (3 refs)

78-6455 Epstein-Barr Virus and Human Chromosomes: Close Association of the Resident Viral Genome and the Expression of the Virus-determined Nuclear Antigen (EBNA) with the Presence of Chromosome 14 in Human-Mouse Hybrid Cells. (Eng) Yamamoto, K. (Dept. Microbiology, Cancer Inst., Hokkaido Univ. Sch. Medicine, 060 Sapporo, Japan); Mizuno, F.; Matsuo, T.; Tanaka, A.; Onoyama, M.; Osato, T. *Proc Natl Acad Sci USA* 75(10): 5551-5559; 1978.

Fourteen hybrid clones derived from fused cultures of human lymphoblastoid FV5 cells and 5-bromodeoxyuridine-resistant mouse fibroblastic MCB2 cells grown in hypoxanthine/aminopterin/thymidine selective medium were examined for the presence of Epstein-Barr virus (EBV) DNA, expression of the virus-determined nuclear antigen (EBNA), and the presence of human chromosomes. When tested 3 months after their isolation, 11 of the hybrid clones were positive for EBNA, but when tested 18 months after their isolation, only 3 clones were positive for EBNA. EBV DNA was detected only in the three clones that were positive for EBNA after 18 months. Chromosome analysis of the hybrid clones showed that human chromosome 14 was common to all three positive clones, whereas this chromosome was not present in any of the nega-

tive clones tested. In 10 subclones isolated from one of the positive clones, a concordant segregation of EBNA, EBV DNA, and chromosome 14 was evident. The data suggest that the resident EBV genome is closely associated with chromosome 14 and that the presence of this chromosome alone is sufficient for the maintenance and expression of EBV genetic information in human lymphoblastoid cells. (20 refs)

78-6456 Studies of Epstein-Barr Virus (EBV)-Associated Nuclear Antigen: Solubilization from Raji Cell Chromatin with 5 M-Urea-2 M-NaCl and Fractionation on Hydroxyapatite. (Eng) Brown, T. D. (Beatson Inst. Cancer Res., Wolfson Lab. Molecular Pathology, Bearsden, Glasgow G61 1BD, Scotland); Rickwood, D.; MacGillivray, A. J.; Klein, G. *J Gen Virol* 40(3): 511-517; 1978.

A ¹²⁵I-IgG absorption assay was used to detect Epstein-Barr virus-associated nuclear antigen (EBNA) solubilized from Raji cell chromatin by treatment of the chromatin with high concentrations of urea and salt. The chromatin was fractionated into histone and nonhistone fractions on hydroxyapatite (HAP), and the nonhistone proteins were subfractionated by a discontinuous elution system. Very little antigenic activity was present in the histone-containing HAP 1 fraction, but activity was readily detected in the three non-histone fractions (HAP 2, 3, and 4). The absorption patterns of HAP 3 and HAP 4 differed, suggesting a fractionation of antigenic specificities. HAP 3 and 4 contained the bulk of the antigenic activity but only 7% of the total chromatin protein. The data suggest that EBNA is a nonhistone chromatin-associated protein. (27 refs)

78-6457 Alkaline Phosphatase in Epstein-Barr Viral Nuclear Antigen-positive Cell Lines. (Eng) Karpas, A. (Dept. Haematological Medicine, Univ. Cambridge, Cambridge, England); Hayhoe, F. G.; Greenberger, J.; Neumann, H. *Science* 202(4365): 318-319; 1978.

Alkaline phosphatase (APase) present in Epstein-Barr viral nuclear antigen (EBNA)-positive, surface membrane immunoglobulin (SmIg)-negative cell lines established from two leukemia patients was characterized. One of the patients had acute myeloid leukemia (AML) and the other a combined B- and T-cell acute lymphoblastic leukemia (ALL). The AML-derived cells contained myeloid APase, as determined by its ability to catalyze the hydrolysis of two types of substrates, ortho-substituted monoesters of orthophosphoric acid (substrate type 1) and the S-substituted monoesters of thiophosphoric acid (substrate type 2) with equal efficiency. The ALL-derived cells contained lymphoid APase, which catalyzes the hydrolysis of substrate type 1 only. Biochemical testing for two types of APase may allow distinction between primitive lymphoid and myeloid cells and may also be useful for detecting APase in cells that are cytochemically negative for the enzyme. The presence of the myeloid-specific enzyme

in an SmIg-negative cell line suggests that the line is composed of myeloid precursor cells and that such cells may be susceptible to infection with Epstein-Barr virus. (14 refs)

- 78-6458 Translocation of a Hydrocarbon Fluorescent Probe Between Epstein-Barr Virus and Lymphoid Cells: An Assay for Early Events in Viral Infection.** (Eng) Rosenthal, K. S. (Harvard Medical Sch., Boston, MA, 02115); Yanovich, S.; Inbar, M.; Strominger, J. L. *Proc Natl Acad Sci USA* 75(10): 5076-5080; 1978.

An assay to determine early biochemical events during cell-virus interactions is described, as well as its application in measuring events following the interaction of Epstein-Barr virus (EBV) with different types of lymphoid cells. The method is based on translocation of the hydrocarbon fluorescent probe diphenylhexatriene (DPH) between viral envelopes and cellular membranes, as monitored by fluorescence polarization (P) analysis. Using a model system, the high P value (0.324) of DPH-labeled cholesterol/phosphatidylcholine liposomes and the low P value (0.157) of DPH-labeled phosphatidylcholine liposomes allowed detection of DPH-translocation between interacting liposomes. This was monitored by the change in P in either direction. The P value of DPH-labeled EBV was significantly higher (p.350-0.392) than the P value of DPH-labeled lymphoid cells (0.238-0.289). Hence, DPH translocation could be detected by changes in P following incubation of DPH-labeled EBV and nonlabeled cells. A marked decrease in P was observed after incubation of DPH-labeled EBV with nonlabeled lymphoblastoid Raji cells or fresh human B lymphocytes. However, only a slight decrease in P was obtained when DPH-labeled EBV was incubated with nonlabeled fresh human T lymphocytes or fresh rabbit T or B lymphocytes. Moreover, incubation of human B lymphocytes with purified complement 3 (a putative inhibitor for the EBV receptor) prior to the addition of DPH-labeled EBV abolished the decrease in the P value. Most of these experiments were carried out with both the P3HR-1 and B95-8 EBV strains. Therefore, DPH translocation, as determined by fluorescence polarization, measures some early event during interaction of this enveloped virus and mammalian cells. The potential applicability of this technique to other viruses is illustrated by an experiment with Semliki Forest virus. (32 refs)

- 78-6459 An Evaluation of Antibody Titers to the Epstein-Barr Virus as a Test for Susceptibility to Cancer.** (Eng) Levine, P. H. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); Connelly, R.; Heath, C. W.; Caldwell, G. G.; Terasaki, P. I.; Mickey, M. R.; Fabrizio, P. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and

Prevention of Cancer. (New York, NY): Vol. 2 (part 1), 2 pp.; 1525-1537; 1978.

Antibodies to Epstein-Barr virus (EBV) capsid antigen (VCA) were studied in 210 normal first-degree relatives of cancer patients from 31 families with multiple cancer cases (MCF). Sera from each relative were matched by age, sex, and sex to a control sample from a normal individual. They were tested for VCA antibodies by immunofluorescence using a procedure using P3HR-1 antigen and Hyland goat anti-human IgG as antisera. VCA titers were significantly higher in normal MCF relatives compared with controls, which suggest that EBV-VCA titers may be indicative of an abnormality predisposing to malignancy. A comparison of EBV-VCA titers and histocompatibility antigens HL-A among patients with Hodgkin's disease or Burkitt's lymphoma and their relatives showed that high titers were not associated with specific HL-A types (A-1, B-5, B-8) linked to lymphoproliferative disease. (27 refs)

- 78-6460 Papain Solubilization of the Epstein-Barr Virus-induced Membrane Antigen.** (Eng) Peterson, G. R. (Dept. Microbiology, Mayo Clinic/Foundation, Rochester, MN, 55901); Qualtiere, L. F. *J Virol* 28: 344-351; 1978.

Epstein-Barr virus (EBV)-induced membrane antigen (MA) was purified and characterized in a series of experiments. EBV-infected Raji cells were exposed to papain (5 to 10 units/ 1×10^7 to 2×10^7 cells) for 1 hr. Membrane immunofluorescence and antibody-dependent cellular cytotoxicity (ADCC) assays of the cells revealed that most of the MA was removed by this treatment. Soluble MA was demonstrated in papain digests through inhibition of ADCC and by inhibition of the binding of anti-MA antibodies to EBV-infected Raji cells, as detected with the use of ^{125}I -labeled staphylococcal protein A. Papain extracts were centrifuged at 100,000 $\times g$ for 1 hr and tested for MA activity in the ^{125}I -protein A test. Approx 75% of this activity remained in the supernatant, indicating that most EBV MA activity in the extract was associated with low-mol-wt material. Antiserum prepared from an owl monkey immunized with the papain extract had no detectable antibodies to viral capsid antigen or early antigen; however, an antibody reactive to EBV-induced MA was present at a titer of 80 and a neutralization titer of 320. (23 refs)

- 78-6461 Isolation of Epstein-Barr Virus (EBV) in Suspensions of Cells Obtained from Patients with Different Hemoblastoses.** (Rus) Agrba, V. Z. (Inst. Experimental Pathology and Therapy, Acad. Medical Sciences, USSR, Moscow, USSR); Iakovleva, L. A.; Lapin, B. A.; Lebedev, V. N.; Grigor'ev, A. S.; Sangulia, I. A.; Timonovskaya, V. V.; Chuvirov, G. N.; Bukaeva, I. A.; Markova,

Markarian, D. S.; Kokosha, L. V. *Vopr Onkol* 24(9): 10; 1978.

sension cultures prepared from peripheral blood lymphocytes of leukemia patients and from lymph node cells and cells from patients with other hemoblastoses were investigated electron microscopically for the presence of Epstein-Barr virus (EBV). Eight virus-producing cell lines were established: 5 from 7 patients with myelogenous leukemia, from 9 patients with lymphogranulomatosis, and 1 from a patient with a lung tumor and a leukemoid reaction. No virus-producing cell lines could be established from three patients with lymphocytic leukemia or from another patient with non-Hodgkin's lymphoma. All eight cell lines produced virus in 0.5%-3% of the cells. The cells of the virus-producing lines were lymphoblasts with B-cell characteristics. (34

462 **Further Studies on the Replication of Adenovirus Type 2 DNA.** (Eng) Raptis, L. (Departement Microbiologie, Faculte de Medecine, Centre Hospitalier Universitaire, Universite de Sherbrooke, Sherbrooke, Quebec Canada J1H 5N4); Delbecchi, L.; Bourgaux, P. *Can J Microbiol* 56(9): 857-865; 1978.

distribution of ³H-thymidine in pulse-labeled replicating adenovirus 2 (Ad2) DNA was determined, and an attempt was made to pinpoint the origin(s) of replication on the Ad2 genome. Monolayer cultures of Ad2-infected KB cells were subjected to short pulses of ³H-thymidine at the time of max viral DNA synthesis. Nascent viral DNA was isolated from the cells, purified, and fractionated into partly completed (C) molecules. The latter were cleaved by *Eco*HindIII, *Hpa*I, or by *Hind*III + *Hpa*I, and the fragments were separated electrophoretically. R molecules were also treated with these enzymes, but the double-stranded fragments were separated from the partly single-stranded fragments by chromatography on benzoylated-naphthoylated diethylaminoethylcellulose before they were subjected to electrophoresis. Analysis of C molecules revealed a strong preferential labeling of fragments derived from the ends of molecules, as expected if both ends contain termini for replication. Analysis of double-stranded fragments from R molecules revealed a predominant labeling of the center of the genome that could be reconciled with initiation occurring internally or at both ends. In addition, two gradients of labeling arising toward each end and encompassing the outer quarter of the molecule, were noted that slowly receded when pulse length was increased. This finding may reflect an overrepresentation of molecules in the late stages of replication in the pool of nascent DNA, and it is to be expected if replication slows down when it nears the termination site(s). This interpretation is consistent with the labeling kinetics of various portions of the genome observed in the pool of molecules. Because of this complication, however, the distribution of label in R molecules cannot be used to determine

the exact location of the origin(s) of replication on the Ad2 DNA. (20 refs)

78-6463 **Size Distribution of Polyadenylated Adenovirus 2 RNA Synthesized in Isolated Nuclei.** (Eng) Zimmer, S. G. (Dept. Pathology, Univ. Kentucky Medical Center, MDRF 3, Lexington, KY, 40506); Goldenberg, C. J.; Carlson, D. P.; Craig, E. A.; Raskas, H. J. *Biochemistry* 17(20): 4207-4213; 1978.

Nuclei isolated from cultures of KB cells 14 hr after infection with adenovirus 2 were studied for their ability to transcribe viral RNA with fidelity and to generate discrete viral RNA size classes from specific regions of the genome. RNA synthesized in vitro was approx 40% viral and was derived almost entirely (95%) from the viral *r* strand. Hybridization-inhibition experiments demonstrated that the in vitro RNA transcripts included two classes of sequences, those restricted to the nucleus in vivo and those in cytoplasmic RNA. Quantitation of viral sequences from defined regions of the genome was performed by exhaustive hybridization with seven viral DNA fragments generated by digestion with endonuclease *R-Eco*R1 or *R-Sma*I. The sizes of the viral RNA synthesized by the KB cell nuclei in vitro were compared with viral RNA labeled by in vivo experiments (whole cell cultures). The polyadenylated viral RNA synthesized in vitro ranged in size from 13S to 28S, with peaks of 28S, 25S, and 22S. The polyadenylated nuclear RNA labeled during a 30-min in vivo pulse was larger, 23S-36S; however, incubation of the prelabeled nuclei in RNA synthesis conditions resulted in a gradual decrease in the size of the prelabeled RNA. RNA prelabeled in vivo contained 36S, 28S, and 22S species that, when incubated under in vitro conditions, were converted to a size distribution identical to that of RNA synthesized by isolated KB nuclei under in vitro conditions. This evidence supports the view that the in vivo and in vitro syntheses of RNA are identical. (46 refs)

78-6464 **Biochemical Studies on Bovine Adenovirus Type 3. IV. Transformation by Viral DNA and DNA Fragments.** (Eng) Igarashi, K. (Biological Res. Labs., Central Res. Div., Takeda Chemical Industries, Ltd., Osaka, Japan); Sasada, R.; Kurokawa, T.; Niiyama, Y.; Tsukamoto, K.; Sugino, Y. *J Virol* 28(1): 219-226; 1978.

Using the calcium technique, mouse cell line A31 (a clone of line BALB/3T3) was transformed in vitro with intact DNA of bovine adenovirus type 3 (BAV3) and also with BAV3 DNA fragments produced by two specific restriction endonucleases. Approx 5 to 10 foci/ μ g of DNA were produced within 20 days of transformation by BAV3 DNA. All foci were composed of round, cuboidal, and densely packed cells. RNase A and Pronase had little effect on the transformation, but DNase was able to abolish it completely. The *Eco*RI fragment D, mapping at 3.6 to 19.7 units, could transform

A31 cells almost as efficiently as intact DNA. No transformation occurred with *Hind*III fragments J, E, and B, but enzymatic joining of J + E (0-11.9 map units) with a ligase restored transforming activity. These results indicate that the genetic information of BAV3 necessary for transformation is located between map units 3.6 and 11.9, comprising 8.3% of the viral genome. Cells transformed by BAV3 DNA, BAV3 DNA *Eco*RI fragment D, and BAV3 *Hind*III fragment J + E (lines Tr, TrD, and TrJE, respectively) all showed the positive nuclear immunofluorescence characteristic of BAV3-transformed cells. Compared with untransformed A31 cells, all transformed lines tested showed rapid growth, high saturation density, and anchorage-independent growth. They also contained BAV3-specific tumor antigen. Lines Tr and TrD produced tumors in 100% of nude mice injected in 2 wk, and all three transformed lines produced tumors in 63%-100% of BALB/c mice within 2 mo. (23 refs)

- 78-6465 **Biochemical Studies on Bovine Adenovirus Type 3. III Cleavage Maps of Viral DNA by Restriction Endonucleases *Eco*RI, *Bam*HI, and *Hind*III.** (Eng) Kurokawa, T. (Biological Res. Labs., Central Res. Div., Takeda Chemical Industries, Ltd., Osaka, Japan); Igarashi, K.; Sugino, Y. *J Virol* 28(1): 212-218; 1978.

The restriction endonucleases *Eco*RI, *Bam* and *Hind*III were used to construct cleavage maps of bovine adenovirus type 3 (BAV3) DNA by analyzing overlapping sets of specific fragments produced by the enzymes and by cleavage of DNA previously end-labeled by T4 DNA polymerase. After digestion, fragments were analyzed by gel electrophoresis. *Bam*HI yielded 5 fragments (A-E); *Eco*RI, 7 (A-G); and *Hind*III, 12 (A-L). The order of fragments on the the DNA molecule was determined by overlapping the specific fragments produced by two different restriction endonucleases. The order was GDACBFE for the *Eco*RI fragments, AEBDC for the *Bam*HI fragments, and JEBKACDHFGIL for the *Hind*III fragments. The BAV3 preparation contains a unique population of incomplete virus whose genome has a deletion of 13% of the complete virus genome. Restriction endonuclease digestion of the incomplete virus DNA revealed that *Eco*RI E and F, *Bam*HI C, and *Hind*III G, I, and L fragments were missing. Therefore, the deleted region of incomplete virus DNA is located near the right end of complete virus DNA, a result consistent with previous electron microscope observations of heteroduplex molecules formed between complete and incomplete BAV3 DNA. (22 refs)

- 78-6466 **Transcription of Viral Sequences in Cells Transformed by Adenovirus Type 5.** (Eng) Frolova, E. I. (Inst. Molecular Biology, Acad. Sciences USSR, Moscow, USSR); Zalmanzon, E. S. *Virology* 89(2): 347-359; 1978.

Viral genomes and their transcription and chromatin conformation were studied in five lines of adenovirus 5 (Ad5)-trans-

formed rat embryo cells. Renaturation experiments showed that all lines contained sequences homologous to *Hpa*I fragment E, but they varied in other Ad5 DNA sequences. Any viral functions required for maintaining the transforming phenotype are encoded by the left end of Ad5 DNA. All viral DNA sequences in the three lines studied were transcribed into nuclear RNA. Only part of the sequences of I fragment E in all lines were sensitive to DNase I. (23 refs)

- 78-6467 **The Relationship Between T Antigens of group A and B Adenoviruses.** (Eng) Shirokawa, H. (Inst. Medical Science, Univ. Tokyo, Shirokawa Minato-ku, Tokyo 108, Japan); Shimojo, H.; Sekikawa, K. *Virology* 89(2): 627-631; 1978.

The relationship between the tumor antigens (TAgs) of groups A and B adenoviruses was investigated by immunofluorescence and DNA-DNA hybridization experiments. Secondary cultures of human embryo kidney cell 3Y1 cells (a line derived from a Fischer rat embryo) infected with adenovirus 12 (Ad12), Ad31, Ad7, Ad3, and Ad5 (10 plaque-forming units/cell) in the presence of μ g/ml of cytosine arabinoside. After 24 hr, cells were harvested and stained by indirect immunofluorescence with anti-TAg serum. TAg was detected in the nuclei of rats bearing GY1 cell (rat line transformed by the dIII-G fragment of Ad12 DNA) tumors. TAg with the morphology of cytoplasmic flecks and nuclear fibrils was observed in Ad12- and Ad31-infected cells, but TAg predominantly in the form of nuclear fibrils was observed in Ad7 and Ad3-infected cells. Thus, the morphology of TAg seems to be determined by virus type. TAg was not detected in Ad5-infected cells. These observations indicate that TAg is common among members of subgroups A (Ad12, Ad31, and B (Ad7, Ad3) adenoviruses, a conclusion that agrees with the high homology between the *Hind*III-G fragment of Ad12 DNA and Ad31 DNA and with the high homology between the *Hind*III-IJ fragment of Ad7 DNA and Ad3 DNA. In addition, TAg of Ad7 was partially stained by immunofluorescence with antiserum to Ad12 TAg and vice versa. However, the homology between the transforming fragment of Ad12 DNA and Ad7 DNA was only 9%-15%. The discrepancy between the common antigenicity and DNA homology, which also occurs with simian virus 40 and Ad virus, is discussed. (9 refs)

- 78-6468 **Adenovirus-induced Changes in the Weight of the Mouse Spleen and Thymus.** (Rus) Ageeva, A. I. (Lab. Virology, P. A. Hertsen Res. Inst. Oncology, Moscow, USSR); Erkhov, V. S.; Sviridova, I. K. *Biull Eksp Med* 86(9): 356-358; 1978.

In an attempt to detect lymphoid cells with increased proliferative potential, newborn CBA mice were inoculated with simian adenovirus (SA7, C8, 10^4 units/0.1 ml). Twenty days later, the mice were sacrificed and the spleen cells

transferred into newborn syngeneic mice (9×10^6 cells/mouse). The effect of the transfer was measured by changes in the wt of the lymphoid organs in 10-day-old mice. The transfer of splenocytes from mice during the latent period of SA7-induced carcinogenesis resulted in a significant increase in the spleen wt:body wt ratio (5.64, compared with 3.71 after transfer of normal splenocytes and 3.72 in controls) and significant decrease in the thymus wt:body wt ratio (4.04, vs 4.88 and 6.21, respectively). Thus, adenoviral carcinogenesis mimics some manifestations of autoimmune disease. (10 refs)

6469 Transcription Map for Adenovirus Type 12 DNA. (Eng) Smiley, J. R. (Dept. Therapeutic Radiology, Radiology Labs., Yale Univ. Sch. Medicine, New Haven, CT, 06510); Mak, S. *J Virol* 28(1): 227-239; 1978.

The physical locations and strand derivation of the adenovirus type 12 (Ad12) DNA sequences expressed as early and late cytoplasmic RNA (cyRNA) were mapped, and the relative rates of accumulation of this RNA from different regions of the genome were monitored at different times after infection. ^3H -labeled, intact, complementary l- and r-strand DNA fragments were hybridized with saturating amounts of unlabeled late cyRNA extracted 24 hr after infection of human cells with Ad12. The segments of each DNA strand complementary to the RNA were then purified by S1 nuclease digestion of the hybrids. These ^3H -DNA preparations were used as templates for hybridization with unlabeled DNA fragments generated by the restriction endonucleases *EcoRI*, *BamHI*, and *HindIII*. The completed map was very similar to that of Ad2. The subset of the late cyRNA sequences that were expressed at early times was located on the map by hybridizing labeled, early cyRNA to both unlabeled DNA fragments and unlabeled complementary strands of specific fragments. Early cyRNA hybridized to the r strand of *EcoRI*-C, *BamHI*-B and to the l strand of *BamHI*-E. Hybridization with *BamHI*-C was also observed. The relative rates of accumulation of cyRNA complementary to individual restriction fragments was measured at both early and late times. Early after infection, most of the viral RNA appearing in the cytoplasm was derived from the molecular ends of the genome. Later (24-26 hr postinfection), most of the newly synthesized cyRNA was transcribed from DNA sequences mapped between 25 and 60 map units on the genome. (39 refs)

6470 Morphological Revertants of Adenovirus Type 12-Transformed Hamster Cells. (Eng) Grone, G. J. (Inst. Genetics, Univ. Cologne, Cologne, W. Germany); Sutter, D.; Soboll, H.; Doerfler, W. *J Gen Virol* 40(3): 635-645; 1978.

B₁ subline of baby hamster kidney (BHK21) cells, the T637 derived by transformation of this subline with adenovirus type 12, and two morphological revertants of T637 (F10 and G12) were characterized. In contrast to T637

cells, which were round, the revertant lines exhibited a fibroblastic morphology, as did B₁ cells. Unlike B₁ and T637 cells, the revertant cells reacted with anti-LETS (large, external, transformation-sensitive protein) serum. The revertants were also less easily agglutinable by concanavalin A and less likely to form colonies in soft agar than T637, and they resembled B₁ in their uptake of amino acids and 2-deoxyglucose. Judging from the time required to induce tumor growth, G12 and F10 grew less readily in 4-wk-old Syrian hamsters than B₁ and T637 cells. The karyotypes of the four cell lines appeared to be indistinguishable, but the patterns of integrated virus genomes in the revertants differed markedly from that of T637 cells; F10 appeared to have lost all viral DNA sequences. (22 refs)

78-6471 Activated Endogenous Viruses of Tumor Induced by Human Adenovirus: An Electron Microscope Study. (Eng) Ohmori, M. (Dept. Pathology, Okayama Univ. Medical Sch., Okayama 700, Japan). *Exp Mol Pathol* 29(2): 260-271; 1978.

Activated endogenous C-type virus particles (ECP) and intracisternal A particles (IAP) in C3H/BiF₁ mice tumors induced by human adenovirus 12 (Ad12) were studied by electron microscope freeze-fracture-etching techniques. IAP were found in the endoplasmic reticulum (ER) and perinuclear cisternae. The ER membrane was electron dense and protruded into the cisternae to form either a single particle or many particles that were released eventually into the cisternae. The ECP particles began as spherical elevations on the tumor cell membrane; as the particles matured, the surface projections were lost and the particles became polygonal in shape. The production of ECP appeared to be continuous at some cell sites. Because these particles are not seen in chemically induced or in spontaneous tumors of syngeneic mice, it is assumed that Ad12 infection supplies the incomplete, masked genome of an endogenous leukemia virus with the material needed for its proliferation. (31 refs)

78-6472 Nucleotide Sequence Relationship Between Intracisternal Type A Particles of *Mus musculus* and an Endogenous Retrovirus (M432) of *Mus cervicolor*. (Eng) Kuff, E. L. (Lab. Biochemistry, NCI, NIH, Bethesda, MD, 20014); Lueders, K. K.; Scolnick, E. M. *J Virol* 28(1): 66-74; 1978.

The purified high-mol-wt RNA of *Mus musculus* (MM) intracisternal A-type particles was tested for homology with the viral genome of M432, a retrovirus isolated from *M. cervicolor* (MC). Partial nucleotide sequence homology was observed between the 32S and 35S RNA components of A-type particles from neuroblastoma cell line N4 (from a tumor in A/Jax mice) and the 70S fraction from M432. M432 complementary DNA (cDNA) was hybridized to about the same extent (25%-30% of the homologous reaction) by MM cellular

DNA and A-particle RNA; therefore, the entire group of M432-related MM sequences could be represented in the A-particle RNA. The hybrids showed a lower thermal stability than those formed with homologous RNA. The reaction was commensurate with that found between M432 cDNA and divergent sequences in the MM genome. The capacity to hybridize M432 cDNA was correlated closely with the concentration of A-particle sequences in the cytoplasmic RNA of several MM cell types. The major RNA fraction of M432 virus showed a reciprocal partial reaction with the A-particle cDNA's; the virus, which was grown in NIH/3T3 (MM) cells, also contained a small proportion of apparently authentic A-particle nucleotide sequences. However, a portion of the A-particle sequences, the so-called abundant class, seemed to be lacking in M432 genomic RNA. Multiple copies of both M432- and A-particle-related sequences were also present in MC DNA. However, the latter seemed to contain a more complete representation of the intracisternal A-particle information than was found in the M432 virus, since A-particle 35S cDNA was hybridized to a greater extent by MC cellular DNA than would have been expected on the basis of its partial homology with M432 viral RNA, and sequences homologous to the A-particle abundant-class probe were present in the DNA, even though they had no counterpart in the M432 viral genome. 78-6473 Defective C-type Retrovirus Particles Secreted by L1210 Leukemia Cells. (Eng) Kennel, S. J. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Tsakeres, F.; Kelly, P. A.; Allison, D. P. *Cancer Res* 38(12): 4574-4579; 1978.

C-type retrovirus particles released from cultures of L1210 leukemia cells (L1210) were characterized as a first step in determining the effect virus may have on the biology of the L1210 model system. The virus particle was found to be nononcogenic and noninfectious in standard assays for xenotropic and ecotropic murine retroviruses. This L1210 virus had a normal complement of viral proteins except that it had no detectable glycoprotein with a mol wt of 70,000 (gp70). Quantitative radioimmunoassay for the major structural protein, the one with a mol wt of 30,000 (p30), indicated that the virus is at least a thousandfold more defective than ecotropic viruses such as AKR and Moloney leukemia virus. L1210 cells grown in vitro released about 20 times more particle-associated p30 than in vivo-cultured cells, but cell-associated p30 and gp70 were found at similar levels. Both in vitro- and in vivo-cultured cells displayed gp70 on their surfaces that appeared to be of higher mol wt than the gp70 from most ecotropic viruses. Cells grown in vitro released a high level of non-virion-associated gp70 into the growth medium, but the high concentration of gp70 in the serum of normal DBA/2 mice precluded such measurements on in vivo-cultured cells. These results indicate that L1210 virus does not act as a classical infectious leukemia virus during the growth of L1210 cells, but the presence of relatively large amounts of viral antigens in these cells may affect the immune response to them. 78-6474 The Etiology of Laryngeal Papillomatosis. (Eng) Quick, C. A. (Div. Otolaryngology, V. A. Medical Center, Morgantown, WV, 26506); Fawcett, A.; Krzysek, R. *Laryngoscope* 88(11): 1789-1795; 1978.

Virological techniques for isolating whole virus, free viral DNA, or integrated viral DNA were used to determine whether the virus involved in the etiology of laryngeal papillomatosis is human papilloma virus. Human papilloma virus banded at 1.34 g/ml in a cesium chloride gradient; examination of the supernatant from pooled laryngeal papilloma specimens showed no such band, indicating that no virus was present. The electrophoretic mobility of the supernatant from a cutaneous wart was compared with that of markers of known molecular size, and the results were positive for free human papillomatosis virus DNA. When the technique was repeated with laryngeal papillomas, no such band was identifiable in the agarose gel. When integrated viral DNA was assayed by molecular hybridization, human papilloma virus type V showed 100% hybridization, but no hybridization was seen with the laryngeal papillomas. The results suggest that the virus responsible for laryngeal papillomatosis is not the same as the virus responsible for cutaneous papillomatosis lesions and, for the most part, exists in integrated DNA form. 78-6475 Interactions of Shope Papilloma Virus with Some Other DNA Viruses. (Eng) Chardon, Y. (Unite de Virologie Fondamentale et Appliquee, SERM, Groupe de Recherche 33, CNRS, 1, place du Professeur Joseph-Renaut, F 69371 Lyon Cedex 2, France); Grell, T.; Lyon, M.; Sohier, R. *Bull Cancer (Paris)* 65: 195-206; 1978.

The interactions of Shope papilloma virus (SPV) with mouse and rabbit cells in tissue culture were investigated. Rabbit cell cultures were derived from normal epidermis, SPV-infected epidermis, SPV-induced papillomas, and SPV-associated carcinoma. None of these cell cultures, whether infected in vitro with SPV or derived from tissue infected in vivo, produced infectious SPV or detectable viral antigens. Some other DNA viruses behaved differently: cells that had been in previous contact with SPV either in vitro or in vivo. Adenovirus type 5 multiplied better in human cells infected 24 hr previously with SPV than in untreated controls. The production of infectious virions of herpes simplex virus or Shope fibroma virus was reduced in cells derived from SPV-induced papillomas or carcinoma, due to a delay in viral maturation. Of the rabbit cells, only those derived from in vivo infected tissue or those previously infected in vitro with SPV were transformed by simian virus 40. The rabbit cell lines derived from papillomas or carcinoma differed from their counterparts derived from normal epidermis or from tissue infected 24 hr before biopsy in their karyotype and in their ability to grow in soft agar. Similar karyotypic alterations were induced in cells derived from healthy epidermis by infection in vitro with SPV. (29 refs)

- 476 **Heterogeneity of Human Papilloma Viruses.** (Eng) Pfister, H. (Institut für Virologie, Zentrum für Hygiene, Hermann-Herder-Strasse 11, 7800 Freiburg, W. Germany); Gissmann, L. *Bull Cancer (Paris)* 65(2): 67; 1978.

types of human papillomaviruses, HPV-1 and HPV-4, characterized by purifying virions from single skin. Viral DNA was extracted by solubilizing the protein with sodium dodecyl sulfate and then cleaved with different restriction endonucleases. The resulting fragments separated by gel electrophoresis. The results show no relationship between HPV-1 and HPV-4 as far as the following criteria are concerned: the pattern of restriction enzyme fragments of their DNA, DNA-complementary RNA hybridization, and complement fixation with specific rabbit antiserum. Moreover, the mol wts of their major proteins differed significantly. Both virus types could be isolated from plantar warts and from verrucae vulgares. In addition, a third type of HPV was isolated from the skin warts, with HPV-1 or with HPV-4 rabbit antiserum. (10 refs)

- 477 **Mastomys natalensis Papilloma Virus (MnPV), the Causative Agent of Epithelial Proliferation: Characterization of the Virus Particle.** (Eng) Müller, H. (Institut für Virologie, Justus-Liebig-Universität Giessen, Justus-Straße 107, 6300 Lahn-Giessen, W. Germany); Gissmann, L. *J Gen Virol* 41(2): 315-323; 1978.

physicochemical and morphological characteristics of *Mastomys natalensis* papilloma virus (MnPV) were studied. Virus particles banded in CsCl gradients at densities of 1.34 g/ml (full particles) and 1.29 g/ml (empty particles). The DNA had a buoyant density of 1.7104 g/ml, and it existed in three different conformations (supercoiled circular, relaxed circular, and linear). The sedimentation values of the three conformations were 23S-24S, 16S-17S, and 15S, respectively. Although the mol wt of MnPV DNA ($\times 10^6$) was similar to that of human papilloma virus (HPV) DNA, the size of the fragments obtained after cleavage of MnPV DNA with the restriction endonuclease *Hae* III differed from that of HPV cleavage fragments. Polyacrylamide gel electrophoresis showed that virion contained different polypeptides; the major structural protein had a mol wt of 56,000. Skin tumors were induced in 36% of mice infected with purified MnPV (containing approx 150 ng of virus protein), but no cutaneous alterations were observed when the particles were inoculated in the presence of anti-MnPV serum; this indicated that MnPV was the etiologic agent in the skin proliferations. MnPV was reisolated from the experimental tumors. (22 refs)

- 478 **Conditions Leading to the Establishment of the N (a Gene Dependent) and A (a Gene Independent) Transformed States after Polyoma Virus Infection of**

Rat Fibroblasts. (Eng) Rassoulzadegan, M. (Centre de Biochimie, Université de Nice, 06034 Nice, France); Seif, R.; Cuzin, F. *J Virol* 28(2): 421-426; 1978.

Infection of normal rat fibroblasts (FR 3T3) with the early temperature-sensitive mutant (*tsa*) of polyoma virus was shown to lead to either the A or the N phenotype. The choice between A and N was made during the first 5 days at 33°C and primarily depended on the growth potential of the infected cells during that time period. Polyoma *tsa*-transformed A clones were temperature-independent for expression of the transformed phenotype, but N transformants were strongly temperature-dependent. The crucial parameter in the N vs A choice is probably the physiological state of the cells during the early part of transformation, and it is likely that no causal relationship exists between the method of selection and the subsequent mode of maintenance. A transformation occurred in both liquid and agar media when the infected cells were maintained under growth-restricting conditions, such as absence of anchorage and contact inhibition at confluency. N transformation occurred in cells maintained in active growth after virus infection (sparse cultures on a solid substratum). The N and A states were redefined as meaning polyoma *a* gene (or simian virus 40 *A* gene) dependent vs independent for maintenance of the transformed state. (12 refs)

- 78-6479 **Tumor Antigens Induced by Nontransforming Mutants of Polyoma Virus.** (Eng) Silver, J. (Dept. Hematology, Beth Israel Hosp., Boston, MA, 02115); Schaffhausen, B.; Benjamin, T. *Cell* 15(2): 485-496; 1978.

Wild-type polyoma virus and nine independently isolated hr-t mutants of polyoma virus (with an absolute defect in transformation) were studied to determine which tumor (T) antigens they induced during lytic infection in mouse cells. In a variety of cell lines, wild-type virus induced a major T-antigen species with an apparent mol wt of 100,000 daltons and four minor T-antigen species with apparent mol wts of 63,500, 56,000, 36,000, and 22,000 daltons. The hr-t mutants induced a normal 100,000-dalton T antigen but none of the minor wild-type virus species; it did induce antigens with mol wts of 6,000-9,000 daltons. "Point" hr-t mutants induced normal amounts of the 56,000-dalton antigen and reduced amounts of the 22,000-dalton antigen but neither of the other two minor antigens. Ts-a mutants, which have a temperature-sensitive defect in ability to induce stable transformation induced T antigens with the same mobility as wild-type virus, but the 100,000-dalton species was thermolabile compared with the wild-type species. A double mutant virus carrying both a ts-a mutation and a deletion hr-t mutation induced a thermolabile 100,000-dalton antigen but none of the minor species. Cell fractionation studies with productively infected cells were carried out to localize the T-antigen species. (55 refs)

- 78-6480 **Contact Behaviour and Pattern Formation of BHK and Polyoma Virus-transformed BHK Fi-**

broblasts in Culture. (Eng) Erickson, C. A. (Dept. Biology, Yale Univ., New Haven, CT, 06520). *J Cell Sci* 33: 53-84; 1978.

The contact behavior of normal (BHK21/13) and polyoma virus-transformed (BHK21) cell lines was studied using high-resolution, time-lapse cinemicrography combined with scanning electron microscopy. At high density, the BHK21/13 cells were generally organized in monolayered parallel arrays with little crisscrossing of whole cells, whereas the BHK21 cells showed a multilayered, highly crisscrossed arrangement with considerable nuclear overlap. In both cell lines, ruffling was inhibited when contact was made ruffle to ruffle. When BHK21/13 cells contacted each other ruffle to side, strong adhesions occurred with accompanying paralysis of ruffling. Then the contacting cell either changed direction, usually spreading along the side of the contacted cell, or it occasionally continued to protrude and underlap the other cell, although the original adhesions remained. The transformed cells never formed strong ruffle-to-side adhesions, and they usually underlapped each other totally. None of the cells moved over the surface of others (overlapping), and all crisscrossing occurred by underlapping. The BHK21 cells had many fewer side-to-substratum adhesions than the BHK21/13 cells, which could explain the ease with which the transformed cells underlap. (36 refs)

78-6481 Growth Factors Produced by Sarcoma Virus-transformed Cells. (Eng) Todaro, G. J. (Lab. Viral Carcinogenesis, NCI, NIH, Bethesda, MD, 20014); De Larco, J. E. *Cancer Res* 38(11, part 2): 4147-4154; 1978.

The epidermal growth factor (EGF) binding capacity of a variety of normal and transformed cell lines was determined. Simian virus 40 (SV40), polyoma virus, and avian sarcoma virus transformants showed normal levels of EGF binding. Only 5/47 chemically transformed cells had lost their EGF specific receptors. However, the binding levels of all murine sarcoma virus (MSV)-transformed lines tested (mouse, rat, and mink) were altered; in none of the cases was multiplication-stimulating activity (MSA) binding reduced. Thus, loss of EGF receptors after transformation appears to be specifically associated with sarcoma virus transformation. Of the >40 human fibrosarcomas tested, 2 had normal levels of EGF receptors but no MSA receptors. One of the MSA receptor-negative lines was producing a family of related growth polypeptides that interacted with MSA receptors but not with EGF receptors and stimulated cell division in cells of various species. The activities of both the sarcoma growth factor and the MSA-related human fibrosarcoma growth factor were heat-stable, protease-sensitive, and sensitive to disulfide-reducing agents. It appears that the production of the sarcoma growth factor is at least in part the mechanism by which sarcoma viruses transform fibroblasts. One of the ways in which cells become transformed may be by endogenous production of growth factors for which they have receptors

and to which they are capable of responding. This intracellular production of growth polypeptides serves as a constant stimulus for cell division, thereby releasing these cells from the constraints of the normal physiological controls. (29 refs)

78-6482 Replication of Polyoma DNA in Isolated Nuclei. Synthesis and Distribution of Initiator RNA. (Eng) Eliasson, R. (Medical Nobel Inst., Div. of Biochemistry, Karolinska Inst., Stockholm, Sweden); Reichard, P. *J Biol Chem* 253(20): 7469-7475; 1978.

The synthesis and distribution of initiator RNA (iRNA) was studied in nuclei isolated from polyoma virus-infected mouse fibroblasts. The nuclei were incubated for 5 min at 37°C under standard conditions, including 2 mM ATP, ¹⁴C-dATP, ³H-guanosine triphosphate (³H-GTP), and ³²P-GTP. Polyoma DNA was extracted selectively, and replicative intermediates (RI) and iRNA were purified and measured. The frequency with which ATP or GTP was incorporated into iRNA during incubation depended on the ATP/GTP ratio. The total number of 5'-ends of iRNA most equalled the total number of 3'-ends, indicating that most iRNA molecules are complete. Newly synthesized iRNA attached to short Okazaki fragments was first detected at 1.5 min. Between 1.5 and 5 min, iRNA accumulated on longer strands, but little change occurred after 5 min. At times (1.5, 5, 10, and 15 min), there was an unexplained accumulation of iRNA linked to very short strands (25-30 nucleotides in length). Only one-fourth to one-third of the Okazaki fragments contained iRNA. This value was independent of the length of the strands (270 or 95 nucleotides) or incubation time. Since the uniqueness of iRNA is not size, not its nucleotide sequence, it is unlikely that a specific base sequence of the template determines either the beginning or the end of iRNA synthesis. It is suggested that iRNA serves as a primer for the synthesis of Okazaki fragments, and that it is transcribed randomly on the genome during iRNA replication. (32 refs)

78-6483 Polyoma Virus Giant RNAs Contain Tandem Repeats of the Nucleotide Sequence of the Entire Viral Genome. (Eng) Acheson, N. H. (Swiss Inst. Experimental Cancer Res., 1066 Epalinges, Switzerland). *Proc Acad Sci USA* 75(10): 4754-4758; 1978.

The arrangement of viral nucleotide sequences in the late virus-specific RNA's synthesized in polyoma virus-infected mouse cells was studied by electron microscopy of hybrids between purified high-mol-wt viral RNA and the HindII-1 fragment of polyoma DNA, which contains 91% of the viral genome. Hybrid molecules containing a short single-stranded gap (corresponding to the 9% of viral sequence not present in HindII-1), flanked by double-stranded regions, were photographed and measured. Most hybrid molecules

tained no single-stranded loops or branches, demonstrating that all viral sequences are transcribed contiguously and that no nonviral sequences are present in the RNA. In hybrid molecules containing RNA up to 3.5 times the genome length, a repeating structure of single-stranded gaps 8% of genome length was observed interspersed with double-stranded regions 89% of the genome length; therefore, polyoma RNA's contain tandem repeats of the nucleotide sequence of the entire viral DNA. A small proportion of hybrid molecules contained single-stranded branches and deletion loops in characteristic positions, indicating that RNA splicing may occur on high-mol-wt nuclear polyoma RNA. (29 refs)

6484 Characterization of the mRNA's for the Polyoma Virus Capsid Proteins VP1, VP2, and VP3. (Eng) Hunter, T. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Gibson, W. *J Virol* 28(1): 240-253; 1978.

The polyoma virus capsid proteins VP1, VP2, and VP3 of the 126 kD-type polyoma virus were identified following translation of total cytoplasmic RNA in the wheat germ system in the presence of ³⁵S-methionine. Upon sodium dodecyl sulfate-polyacrylamide gel electrophoresis, bands corresponding to the three capsid proteins were evident. The bands were identified from analyses of mock infected cultures. The translation products of RNA selected from total cytoplasmic RNA of infected cells by hybridization to polyoma virus DNA showed a high degree of enrichment for VP1, VP2, and VP3. Fractionation of this virus-specific RNA showed that almost all VP1 messenger RNA (mRNA) activity contains poly-A tails, that a substantial proportion of VP2 and VP3 mRNA activity is poly-A deficient. Further proof of the identity of these proteins was afforded by close agreement of the in vitro and in vivo tryptic peptide maps and by the fact that the mobilities of the in vitro products on two-dimensional gels were the same as those of viral proteins labeled in vivo. Gel electrophoresis of in vitro products synthesized from polyoma virus-specific RNA in the presence of ³⁵S-formylmethionine-transfer RNA(met)(f) showed that all three proteins were labeled. Synthesis of all these proteins was inhibited by 80% with 1 mM-guanosine triphosphate, suggesting that their 5' ends are all capped. The sizes of the major mRNA's for these proteins were determined by gel fractionation to be 4.6 x 10³ daltons for VP1, 8.5 x 10³ daltons for VP2, and 7.4 x 10³ daltons for VP3. It is concluded that all three proteins are synthesized independently in vitro and are virally coded and that each has a discrete mRNA. (37 refs)

6485 Splicing of SV40 Late mRNA Is a Post-transcriptional Process. (Eng) Horowitz, M. (Dept. Genetics, Weizmann Inst. Science, Rehovot, Israel); Laub, J.; Bratosin, S.; Aloni, Y. *Nature* 275(5680): 558-559; 1978.

The splicing of simian virus 40 (SV40) late messenger RNA (mRNA) was investigated by analyzing R-loop structures

formed between nuclear (nu) and cytoplasmic (cy) poly(A)+ RNA's and linear SV40 DNA. R loops were obtained by annealing nu or cy 19S poly(A)+ RNA with double-stranded linear SV40 DNA obtained by cleavage of form I DNA with *Bgl*I or *Taq*I restriction endonucleases. The 5' ends of the nu RNA R loops were closer to the cleavage sites than the 5' ends of the cy RNA R loops. Free leaders were more common at the 5' ends of the cy RNA R loops than at the 5' ends of the nu RNA R loops. The ability of the precursor nu poly(A)+ viral RNA to anneal to the entire length of the late portion of SV40 DNA (approx 0.67-0.17 map units), including the corresponding interruptions between the leaders and the bodies of the cy mRNA's indicates that splicing is post-transcriptional. Splicing may occur in the nucleus before the RNA molecule is transported to the cytoplasm. However, it is possible that splicing occurs during transport or immediately after transport. The excision-ligation reaction in the precursor molecule is presumably carried out by an enzyme(s) that recognizes short base-paired sequences in this molecule. This reaction would represent a novel mechanism in the regulation of gene expression in animal cells. (17 refs)

78-6486 Immunocytochemical Evidence for SV40-Related T Antigen in Two Human Brain Tumours of Ependymal Origin. (Eng) Tabuchi, K. (Dept. Neurological Surgery, Okayama Univ. Medical Sch., 2-5-1 Shikata-Cho, Okayama 700, Japan); Kirsch, W. M.; Van Buskirk, J. J. *Acta Neurochir (Wien)* 43(3/4): 239-249; 1978.

Direct and indirect immunoperoxidase techniques were used to screen 39 human brain tumors for the presence or absence of simian virus 40 (SV40) T antigen. The tumors included 13 glioblastomas, 5 astrocytomas, 1 ependymoma, 1 oligodendroglioma, 1 choroid plexus papilloma, 2 medulloblastomas, 1 neurinoma, 10 meningiomas, 1 hemangiopericytoma, 1 angiofibroma, and 3 metastatic cancers. The nuclei of the ependymoma and the choroid plexus papilloma exhibited a strong positive reaction for T antigen. The remaining 37 tumors were negative for the antigen. In the ependymoma, the presence of T antigen was confirmed by a complement-fixation assay of tumor extract. It is noted that the majority of hamster intracerebral tumors induced by papovaviruses are ependymomas or choroid plexus papillomas. (42 refs)

- 78-6487 Evidence of Acquired Immune Deficiencies in Mediterranean Lymphoma. A Possible Aetiological Link.** (Eng) Al-Saleem, T. I. (Dept. Pathology, Coll. Medicine, Univ. Baghdad, Baghdad, Iraq). *Lancet* 2(8092, part 1): 709-712; 1978.

Cellular and humoral immunity was systematically studied in 57 patients with α heavy-chain-positive or -negative Mediterranean lymphoma (ML) and 425 controls (healthy volunteers and patients with minor illnesses or other types of lymphoma). Patients with ML had statistically significant reductions in serum IgG and IgM, whereas patients with Hodgkin's disease and nonintestinal non-Hodgkin's lymphoma did not. Impaired cellular immunity was observed in 50% of ML patients challenged with two recall antigens (mumps and purified protein derivative of tuberculin) and with dinitrochlorobenzene. Comparable anergy was found only in patients with advanced Hodgkin's disease. It is hypothesized that repeated exposure of the intestinal epithelium to *Vibrio cholerae* toxin and/or other biologically similar enterotoxins may produce local (and possibly delayed) general impairment of immunity and thus predispose the patient to the development of lymphoplasmacytic neoplasia. Animals that are genetically susceptible to autoimmune disease may be useful as experimental models to test this hypothesis. (35 refs)

- 78-6488 Role for Monocyte-Macrophage-derived Colony-stimulating Factor and Prostaglandin E in the Positive and Negative Feedback Control of Myeloid Stem Cell Proliferation.** (Eng) Kurland, J. I. (Dept. Medicine, UCLA Medical Center, Los Angeles, CA); Broxmeyer, H. E.; Pelus, L. M.; Bockman, R. S.; Moore, M. A. *Blood* 52(2): 388-407; 1978.

Female B6D2F₁ mouse peritoneal macrophages and human peripheral blood monocytes elaborated colony-stimulating factors (CSF) that stimulated the proliferation in vitro of a class of hematopoietic progenitor cells (colony-forming units-culture, CFU-C) restricted to granulocyte and monocyte-macrophage differentiation. High numbers of monocyte-macrophages had little stimulating activity and were markedly suppressive because of the accumulation of a dialyzable, non-species-specific inhibitor of CFU-C proliferation identified by radioimmunoassay as prostaglandin E (PGE). PGE levels correlated inversely with the incidence of the CFU-C, or committed myeloid stem cells. Indomethacin suppression of PGE synthesis increased the number and size of myeloid colonies stimulated, allowing more accurate estimates of CFU-C incidence. The dose-dependent stimulation of PGE synthesis by macrophages in response to increasing

concentrations of CSF was accompanied by progressive CFU-C inhibitory activity. When human monocytes were exposed to an extract of human granulocytes that decreased CSF production, monocyte PGE synthesis was reduced significantly. The findings indicate that the in vitro proliferation of committed myeloid stem cells is regulated by both positive and negative feedback controls involving monocyte-macrophage-derived CSF and PGE, respectively. The balance between CSF and PGE, factors with mutually opposing actions, is determined by an afferent feedback mechanism operating via the intrinsic modulation of macrophage PGE synthesis in response to local elevations in CSF concentration. (44 refs)

- 78-6489 Age-dependent Leukemia Produced in Thymectomized AKR Mice by Antiserum to Leukemic Cells.** (Eng) Kohn, R. R. (Inst. Pathology, Case Western Reserve Univ., Cleveland, OH, 44106); Sciotto, C. G.; Hensley, S. *Exp Gerontol* 13(3/4): 181-187; 1978.

The hypothesis that immunological attack can cause malignant transformation was tested by treating thymectomized (Th-x) AKR mice of different ages with rabbit antiserum against leukemic cells (ALS), antiserum to nonleukemic cells (ANS), and normal rabbit serum (NRS). Groups of young and old non-Th-x mice were also treated with antisera. There were three series of experiments, one with 366-day-old mice, one with 439-day-old mice, and one with seven survivors of Th-x controls from the first series treated at 500 days of age. Leukemic deaths and ages at death were determined. In the first series, by 500 days of age, 9/10 intact mice but only 3/10 Th-x mice had died of leukemia, and deaths in the latter were delayed. Three out of five Th-x mice receiving ANS and 1/5 receiving NRS died from leukemia. All five Th-x mice that received ALS died from leukemia soon after treatment. In the second series, among Th-x controls and mice receiving NRS, only one died from leukemia by 500 days of age. On the other hand, 3/7 mice receiving ANS died from leukemia by 500 days of age. In the third series, when ALS was given to 500-day-old Th-x mice, the results were equivocal: there were 2 early leukemia deaths, 2 early nonleukemic deaths, and 3 survivors. Antisera given to non-Th-x mice did not significantly affect the age at which leukemia developed. However, there was no clear leukemia-producing effect of antisera in Th-x mice > 500 days old. The leukemogenic effect of antiserum in Th-x mice correlated with the antiviral (Gross leukemia virus) activity of the serum; the ALS interacted most effectively with the virus and caused the highest incidence of leukemia. It is concluded that leukemic transformation is a response to immunological attack on the virus or on cells expressing viral antigens and that an additional age-dependent factor is required for leukemogenesis. 6490 Macrophages and Resistance to Tumors. II. Influence of Agents Affecting Macrophages and Delayed-Type Hypersensitivity on Resistance to a Tumor Inducing Specific 'Sinecomitant' Immunity: Acquired Resistance as an Expression of Delayed-Type Hypersensitivity. (Eng) Nelson, M. (Kolling Inst. Medical Res., Royal North Shore Hosp., Sydney, St. Leonards, New South Wales 2065, Australia); Nelson, D. S. *Cancer Immunol Immunother* 4(2): 107; 1978.

The influence of agents affecting macrophages and delayed-type hypersensitivity (DTH) on resistance to the 3-methylcholanthrene-induced fibrosarcoma H-7 (to which specific resistance can be induced by a low, non-tumorigenic dose of cells) was determined in CBA/H/WEHI mice. The expression of DTH to sheep RBC was inhibited by carrageenan (CG: 2 mg/mouse ip), niridazole (200 mg/kg po), reserpine (RP: 1 mg/kg iv), and by whole-body irradiation (450 and 550 rads, ^{60}Co source, 37 r/min). The specific resistance of immunized mice (2.5 x 10^5 viable cells sc, 17, 18, or 21 days prior to challenge) to pad challenge with H-7 cells was also inhibited by these agents, as shown by progressive tumor growth in the feet. Tumor growth in the feet of nonimmunized mice was not affected by radiation or niridazole, but it was inhibited or delayed by CG, depending on the dose of tumor cells injected. CG permitted the emergence of tumors from an inoculum of 10^4 cells, reduced tumor growth from 5×10^4 cells, had no effect on growth from 10^5 cells, and increased tumor growth from 5×10^5 cells. Also, CG treatment just before challenge with 5×10^5 cells led to tumor growth early after challenge, but CG treatment 16-19 days before challenge led to some restriction of growth. Paradoxically, RP inhibited tumor growth in nonimmune mice profoundly, which suggests that some inflammatory reaction may be necessary for survival of tumor cells injected into the footpad. It was suggested that specific, acquired resistance to H-7 is genetically akin to DTH and that mice offer some natural resistance to this tumor. (36 refs.)

6491 Tumor Induction in Host-Versus-Graft Disease. I. Clinical and Pathologic Features. (Eng) Cornejo, E. A. (Dept. Diagnostic Radiology, Yale Univ. Sch. of Medicine, 333 Cedar St., New Haven, CT, 06510). *Am J Pathol* 109(3): 675-688; 1978.

Inbred C57BL/1 mice given injections of (SJL/J x C57BL/1) F_1 spleen cells developed a runting syndrome designated host-vs-graft disease (HVGd). Mortality from the disease was related to the dose of F_1 cells. Acute pathologic changes resembled those occurring in parent- F_1 graft-vs-host disease (GVHD), although plasmacytosis was more pronounced. Mice who recovered from HVGd showed a slight increase in lymphoma incidence over control mice. Such mice were hyperreactive to the F_1 cells used to initiate the original HVGd syndrome. Most of the tumors developed in those animals receiving the initial injection of F_1 spleen cells within

24 hr of birth. Tumor incidence was unrelated to the clinical severity of HVGd. By contrast, GVHD in the same strain combination resulted in a much higher incidence of lymphomas in a much shorter time. Parental strain cells were detectable in the F_1 hosts up to the time of tumor development. HVGd has a low tumor induction potential; GVHD has a high tumor induction potential. (29 refs)

78-6492 Transfer of Viable Putative Preneoplastic Hepatocytes to the Livers of Syngeneic Host Rats. (Eng) Laishes, B. A. (McArdle Lab. Cancer Res., Univ. Wisconsin, Madison, WI, 53706); Farber, E. *J Natl Cancer Inst* 61(2): 507-512; 1978.

A new technique for the transfer of freshly isolated, carcinogen-altered hepatocytes containing the marker γ -glutamyl transpeptidase (GT) from male F344 albino rats to syngeneic host rat livers is described. Donor mice were inoculated on day 1 with diethylnitrosamine (200 mg/kg ip), fed 2-acetylaminofluorene (2-AAF: 0.02% of diet) on days 14-28, and given a two-thirds hepatectomy (PH) on day 21; cells were isolated on day 31. Hepatocyte suspensions were prepared by proteolytic enzyme perfusion, and transfer was effected by infusion of 0.3 ml of suspension into the hepatic portal vein of rats that had been fed a control diet or the 2-AAF diet for 7 days. All recipients underwent PH on day 7 or 10. Selective proliferation of GT-positive hepatocytes was induced in the livers of hosts that had been fed 2-AAF: large, macroscopic colonies of altered hepatocytes were generated within 10 days of cell transfer. Quantitation of the number of colonies revealed that prior treatment of hosts with a low dose of 2-AAF was essential for the appearance of large numbers of foci. In addition, the appearance of foci on day 10 depended on the presence of intact, GT-positive hepatocytes in the transferred cell suspensions. (24 refs)

78-6493 Tumor-associated Transplantation Antigen Distinct from H-2k-like Antigens on a BALB/c (H-2d) Fibrosarcoma. (Eng) Parmiani, G. (Div. Experimental Oncology A, Istituto Nazionale per lo Studio e la Cura dei Tumori, Via G. Venezian 1, 20133 Milan, Italy); Meschini, A.; Invernizzi, G.; Carbone, G. *J Natl Cancer Inst* 61(5): 1229-1234; 1978.

To determine whether the foreign H-2.1, H-2.5, H-2.11, H-2.23, and H-2.25 antigens on the 3-methylcholanthrene (3-MC)-induced (H-2d) fibrosarcoma C-1 of BALB/cLacDp (C) mice represent the tumor's individual tumor-associated transplantation antigen (TATA), in vivo immunogenicity tests were performed in C mice (H-2d) and in a variety of hybrids of various haplotypes. The C-1 tumor lost its immunogenicity completely in CC3F $_1$ mice (H-2d x H-2k) and partially in CAF $_1$ mice (H-2d x H-2a). Multiple immunizations with C-1 cells in C and hybrid mice showed that C mice had in vivo resistance to tumor challenges of 10^5 C-1 cells

(anti-TATA immunity) and production of antibodies to H-2k antigens, as revealed by a complement-dependent cytotoxicity assay of normal C3Hf/HeDp (C3) lymphocytes. No effector lymphocytes to H-2k antigens were found in mice that had detectable levels of anti-H-2k antibodies. CC3F₁ animals were unable to mount both anti-TATA and anti-H-2k immune responses, whereas CAKF₁, CBRF₁ (both *H-2d* x *H-2k*), and, to a lesser extent, CAF₁ mice displayed anti-TATA immunity in the absence of anti-H-2k antibody production. CD2F₁ (*H-2d* x *H-2d*) mice behaved like C mice, whereas CB6F₁ (*H-2d* x *H-2b*) and CNIHF₁ (*H-2d* x *H-2q*) crosses were resistant to tumor challenge but had lower titers of anti-H-2k antibodies than C mice. Anti-H-2k antibody production in C mice peaked after the sixth immunization, with a very low level being evident after one or two immunizations, when a clear antitumor immunity was present. It is concluded that H-2k antigens and TATA are probably independent antigenic entities on C-1 cells. (13 refs)

78-6494 Stimulating Capacity of Blast Cells from Patients with Chronic Myelocytic Leukaemia, in Blastic Crisis in 'One-Way' Mixed Lymphocyte Reaction: Lack of Evidence for T Lymphoblastic Conversion. (Eng) Han, T. (Depts. Medicine B and Immunology Res., Roswell Park Memorial Inst., New York State Dept. Health, Buffalo, NY, 14263); Gomez, G. A.; Minowada, J. *Immunology* 35(2): 299-305; 1978.

The stimulatory capacity of fresh leukemia blast cells from patients with Philadelphia chromosome (Ph¹)-positive chronic myelocytic leukemia-blastic crisis (CML-BC, 6 patients), acute myeloblastic leukemia (AML, 10), and T- and null-cell type acute lymphoblastic leukemia (ALL, 1 and 5, respectively) on allogeneic lymphocytes in one-way mixed lymphocyte reactions was studied. The blast cells from the CML-BC patients significantly stimulated the allogeneic T lymphocytes. The degree of stimulation increased with the number of blast cells, and there was no apparent difference in stimulatory capacity between myeloid-type and lymphoid-type blasts. The blast cells from the AML patients and from three with null-cell ALL also stimulated allogeneic lymphocytes, but cells from the patient with T-cell ALL and cultured leukemic T lymphoblastoid cells (2 lines) showed no stimulating capacity. The cells from two patients with null-cell ALL were not stimulatory. However, cultured leukemic null cells (4 lines) consistently exerted a strong stimulation in the mixed lymphocyte reaction. The data suggest that leukemic cells from patients with lymphoblastic type CML-BC are not T lymphoblasts, although the possibility that they are non-T/non-B lymphoblasts cannot be ruled out entirely. (22 refs)

78-6495 Cell-mediated Lympholysis: A Receptor-associated Lytic Mechanism. (Eng) Gensheimer, G. G. (Transplantation Biology Section, Immunology

Branch, NCI, NIH, Bethesda, MD, 20014); Neefe, J. R. *Immunol* 36(1): 54-64; 1978.

The mechanism of cell-mediated lympholysis was investigated. Two major hypotheses have been proposed to explain the relationship between the binding stage and the killing stage: (1) lysis is a nonspecific result of the intimacy created between killer and target by specific antigen-receptor binding and (2) lysis is effected by the killer cell receptor itself or a closely linked cell-surface component. Two populations of cytotoxic effector cells were coincubated, one relevantly sensitized to the second and the second irrelevantly sensitized to a third party; in some cases the third-party cells were added. Relevantly sensitized killers were not lysed when coincubated with either cytotoxic targets alone or with cytotoxic targets and their appropriate third-party targets. It is clear, therefore, that the lytic event in cell-mediated killing is not simply a result of the intimacy created by attacker-target binding. In addition, receptor accommodation does not produce an activated state in which killer cells secrete nonspecific soluble toxic factors. These findings suggest, rather, that the lytic event in cell-mediated lympholysis is accomplished by the receptor itself or by a geographically close linked cell-surface component. (17 refs)

78-6496 Characterization of T Antigens in Polyoma Virus-Infected and Transformed Cells. (Eng) Hutcheson, M. A. (Tumor Virology Lab., Salk Inst., PO Box 18380, San Diego, CA, 92112); Hunter, T.; Eckhart, W. *Cell* 15: 65-77; 1978.

The immunoreactive proteins [tumor (T) antigens] in polyoma (Py)-infected 3T6 cells were characterized. The virus codes for three species having apparent mol wts of 90K, 60K, and 22K, as determined by polyacrylamide gel electrophoresis. The 90K and 22K species produced by a large- and a small-plaque wild-type Py virus have similar mobilities, but the 60K species produced by the small-plaque wild-type virus has a higher mobility than the 60K species produced by the large-plaque form. The relationship of the virus-coded 90K, 60K, and 22K T antigens to each other is of interest in view of the existence of at least two different genetically defined early viral functions. These functions are defined by two classes of mutants, the temperature-sensitive tsA mutants and the host-range nontransforming hr-t mutants. The 90K species is affected by the tsA mutations, since this species is unstable at the nonpermissive temperature in cells infected by seven tsA mutants. The 60K and 22K species are stable under the same conditions. Only the 22K species is present in cells infected by a mutant carrying a deletion between roughly 98 and 3 map units in the early region of the viral genome. Tryptic peptide analysis of the isolated 90K, 60K, and 22K species shows that the three have few peptides in common. These peptides may be derived from a common N terminal region. The 60K and 22K species contain amino acid sequences not found in the 90K species, and the 60K species has several unique methionine-containing

ides not found in the 22K or 90K species. The observation that two BHK cell lines transformed by Py virus do not contain detectable amounts of the 90K T antigen is consistent with previous observations that permissive or semipermissive Poma-transformed cells fail to contain stable cytoplasmic T antigen corresponding to the distal portion of the early region of the Py genome. The tsA function may be involved in regulating the growth properties of some transformed cells, because some cells transformed by a Py tsA mutant show temperature-dependent growth properties. (27 refs)

6497 Specificity and Age of Appearance of Natural Immunity to MTV Antigens. (Eng) Lopez, D. (Lab. Virology, Dept. Microbiology, Univ. Miami, Sch. of Medicine, Miami, FL, 33152); Sigel, M. M.; Ortiz-Muniz, G.; and others. *Proc Soc Exp Biol Med* 158(1): 23-27; 1978.

The natural immune reactivity of BALB/c mice to mammary virus (MTV) antigens was examined by lymphocyte transformation and migration inhibition assays. The specificity of the lymphocyte response to RIII MTV was measured by virus neutralization reactions using anti-MTV and anti-mouse leukemia virus (abtu-RLV) sera. The former induced the blastogenic response to MTV, but the latter had no effect. RLV did not induce transformation in BALB/c lymphocytes. MTV-induced lymphocyte transformation was observed at low levels and in a small percentage of BALB/cRgl mice as early as 2 wk after birth. At 8 wk of age, the responses in the lymphocyte transformation and migration inhibition assays were intermediate in frequency and/or intensity, and by 16 wk, essentially maximal responses were seen. The nature of the antigen responsible for the lymphocyte sensitivity has not been determined, but radioimmunoassays have largely ruled out the MTV p14 antigen. It is hypothesized that lymphocyte sensitivity to MTV antigen originates from the occurrence of a viral antigen produced by the expression of part of the viral genome in the host cytoplasm. 6498 Leukaemia Associated Antigens: Expression by Human Cell Lines. (Eng) Bertoglio, J. (Laboratoire d'Immunologie et de Cancerologie Experimentale, Centre Leon Berard, 28 rue Laennec, 69373 Lyon Cedex 2, France); Dore, J. F. In: *Human Lymphocyte Differentiation: Application to Cancer. Proceedings of the International Symposium on Human Lymphocyte Differentiation: Its Application to Cancer, held in Montpellier (France) by Institut National de la Sante et de la Recherche Medicale and Delegation Generale a la Recherche Scientifique et Technique, 2-4 March, 1978.* Serrou, B., Rosenfeld, C., eds. (Amsterdam: North Holland Publishing Company); 423 pp.; 357-364; 1978.

Thirteen human lymphoid cell lines derived from normal B lymphocytes or from patients with leukemia, lymphoma, or

Burkitt's lymphoma were tested for expression of leukemia-associated antigens using sera from leukemia patients and normal donors cytotoxic to human leukemia cells and relatively specific for acute lymphoblastic leukemia (ALL). None of the lines derived from the normal B lymphocytes or from patients with Burkitt's lymphoma were reactive. Only four lines, derived from patients with ALL, acute myelomonocytic leukemia, the blastic crisis of chronic myeloid leukemia, and lymphosarcoma, respectively, were reactive with one or more of the 10 sera used. The Reh line, derived from a patient with non-T, non-B ALL, was the most reactive and the only one to react with patients' sera. Cells from a fifth line (derived from a patient with ALL) were able to absorb the reactivity of one serum (MOR: from the father of a leukemia patient) to ALL cells, as were all three cell lines that were reactive with serum MOR in the direct test. Thus, permanent cell lines of leukemic origin may be useful in the study of leukemia-associated antigens. (19 refs)

78-6499 Humoral and Cellular Immune Response of Prostatic Cancer Patients to Cytomegalovirus-related Antigens. (Eng) Sanford, E. J. (Div. Urology, Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033); Geder, L.; Dagen, J. E.; Laychock, A.; Rohner, T. J.; Rapp, F. *J Surg Res* 24(5): 404-408; 1978.

The association between prostatic adenocarcinoma and cytomegalovirus (CMV) infection was investigated in patients with biopsy proved adenocarcinoma or benign prostatic hypertrophy (BPH). Humoral immune response studies were performed to detect antibodies against human embryonic lung cells (HEL), HEL transformed by CMV (CMV-Mj-HEL-2), and cells from a CMV-Mj-HEL-2-induced tumor in nude mice (CMV-Mj-HEL-2, T-1). Neither the cancer nor BPH patients had antibodies against HEL or CMV-Mj-HEL-2 cells, but 80% of the cancer patients and 68% of the BPH patients had antibodies against CMV-Mj-HEL-2, T-1. In cellular immune response studies, 82% of the cancer and 35% of the BPH patients had lymphocytes cytotoxic to CMV-Mj-HEL-2 cells, 82% and 90%, respectively, had lymphocytes cytotoxic to CMV-Mj-HEL-2, T-1 cells, and 20% of both groups had significant cytotoxicity to HEL cells. Sera from prostatic carcinoma patients significantly blocked the cytotoxicity of lymphocytes from prostatic cancer patients against CMV-Mj-HEL-2, T-1 to a greater degree than it did lymphocytes from nontumor controls. Sera from the nontumor controls exhibited little blocking activity. Hyperimmune rabbit anti-CMV sera did not block the cytotoxicity of cancer patient sera and, in fact, enhanced the cytotoxic effect in 2/3 patients. The results suggest that prostatic carcinoma patients possess a serum blocking factor that may be a CMV-related antigen-antibody complex. (18 refs)

78-6500 Specific Immune Response Against Tumor-associated Antigens of a Syngeneic Simian Virus

40-induced Sarcoma in Mice. (Eng) Glaser, M. (Lab. Cell Biology, Immunology Program, Div. Cancer Biology and Diagnosis, NCI, NIH, Bethesda, MD, 20014). *J Natl Cancer Inst* 61(5): 1351-1355; 1978.

An immune response against syngeneic simian virus 40 (SV40)-induced tumor-associated antigens (TAA) in (BALB/c x C57Bl/6)F₁ female mice was detected by in vivo tumor challenge and tumor cell neutralization tests and by the in vitro ⁵¹Cr-release cytotoxicity assay. All mice immunized with 1 x 10⁵ SV40-transformed cells were protected against the growth of SV40-induced tumor from 3 to 90 days after a single immunization. In the tumor cell neutralization test, spleen cells (T cells) from mice immunized with 1 x 10⁵ transformed cells prevented tumor growth from 10 to 90 days after immunization. Spleen cells from mice immunized with a minimum of 20 x 10⁴ transformed cells were cytotoxic in vitro against the relevant target cells in a 4-hr ⁵¹Cr-release cytotoxicity assay. Cytotoxic lymphocytes were detected 3 days after immunization, reached a peak activity at 8 days, and declined to low levels at 14 days. At all times after immunization, T cells were needed for cytotoxic reactivity to be eliminated by specific anti- θ serum and complement. (21 refs)

78-6501 Stimulatory Effect of Immunization on Tumor Induction by Moloney Murine Sarcoma Virus. (Eng) Murasko, D. M. (Dept. Microbiology, Medical Coll. Pennsylvania and Hosp., 3300 Henry Ave., Philadelphia, PA, 19129); Prehn, R. T. *J Natl Cancer Inst* 61(5): 1323-1327; 1978.

Adult BALB/c mice were immunized with varying doses of inactivated Moloney murine leukemia virus (M-MuLV) and challenged 8 wk later with 0.1 ml Moloney murine sarcoma virus (M-MuSV), at a dose that induces tumors in 50% of normal animals. Sera from all immunized mice demonstrated neutralizing activity 14 days after immunization in the XC assay. The ability of sera to neutralize M-MuLV was directly related to the amount of M-MuLV used for immunization. No neutralizing activity was detected in any serum sample taken 8 wk after immunization. Mice immunized with high doses (10¹⁰ particles) of M-MuLV had significantly decreased tumor incidences, whereas mice immunized with low doses (10² particles) had significantly increased tumor incidences, compared with those in nonimmunized controls. The stimulatory effect could be abrogated by irradiation of the mice with 450 rads 24 hr prior to M-MuSV challenge, but the inhibitory effect was resistant to this treatment. The results suggest that depending on dose, immunization with virus can either stimulate or inhibit virus-induced tumorigenesis. Two possible explanations for the mechanism of increased tumorigenesis are suggested: (1) direct stimulation of target cells by lymphoid cells or lymphoid cell products; and (2) suppression of an inhibitory immune response. (33 refs)

78-6502 Resurgence of Killing and In Vivo Protection Mediated by Lymphocytes Cultured from

Lymph Nodes Draining Moloney Sarcomas. (Eng) Gilles, G. Y. (Dept. Pathology, Univ. North Carolina Sch. Medicine, Chapel Hill, NC, 27514); Hansen, C. B.; Russell, S. *Br J Cancer* 38(3): 365-374; 1978.

The return of cytolytic activity to tumor-draining lymph node cells that were no longer cytotoxic in vivo was investigated. The popliteal and lumbar lymph nodes draining progressing or progressing Moloney sarcomas in male BALB/c AnCr mice were removed from the animals and minced, the lymphocytes were isolated. The lymph node cells were no longer cytotoxic in vivo spontaneously regenerated peak levels of killing after a 4-day in vitro culture in the absence of exogenous tumor antigen. Cytolytic activity which was antigenically specific, was mediated by T cells. Resurgence of cytolytic activity in vitro was accompanied by proliferative changes (DNA synthesis, blast transformation, cell division) that peaked on day 3 of culture. Although normal, nonimmune lymph node cells underwent quantitatively similar proliferative changes in culture, the killing that developed was weak and antigenically nonspecific. Transfer of cultured, tumor-draining lymph node cells to immunologically compromised, syngeneic mice conferred complete protection from Moloney sarcoma progression. Adoptive transfer could be delayed for 6 days after tumor induction without loss of protection. These findings suggest that some mechanism in Moloney sarcoma-bearing mice limits the differentiation of prekiller cells into cytolytically active T cells and that this inhibition is eliminated when the lymph node cells are explanted into culture. (31 refs.)

78-6503 Activation of Complement by Spontaneous Leukemic Cells of AKR Mice. (Eng) Okada, H. (Dept. Bacteriology, Kitasato Inst., Shirogane 5-9-1, Minato-ku, Tokyo 108, Japan); Okada, H. *Int J Cancer* 22(2): 282-287; 1978.

The extent of nonspecific activation of complement (NAC) by AKR mouse spontaneous leukemic and normal cells was compared by the human erythrocyte (E) rosette formation following treatment of cells with C4-deficient guinea pig serum in the presence of Mg²⁺/gelatin veronal-buffered saline/ethyleneglycolbis(β-aminoethyl ether) N,N'-tetraacetate (EGTA) and in the absence of Ca²⁺. Following treatment, 10%-30% of lymphoma cells and 10%-17% of thymoma cells formed rosettes, vs only 3%-4% of thymus and mesenteric lymph node cells from nonleukemic mice. The percentage of NAC-positive cells was essentially the same for the original spontaneous, transplanted (to nonleukemic mice), and cultured lymphoma cells, indicating that NAC ability does not result from antigen-antibody-complement complexes that are formed or fixed in vivo. The results suggest that NAC ability may be increased when normal AKR cells become transformed into leukemic cells and/or that leukemic cells arise from thymus cells that possess NAC ability. This interpretation was confirmed further by the finding that a higher proportion of leukemic cells than that of normal

neocytes were lysed by mouse complement in Mg^{2+} -A. The fact that NAC-positive AKR thymoma cells are lysed more effectively by homologous C3H/He mouse serum than by the guinea pig serum agrees with earlier findings that a temporary regression of leukemia occurs in leukemic AKR mice supplemented with C5. (30 refs)

6504 **Characterization of Fc Receptor in Human Malignant Tumors (Meeting Abstract).** (Eng) Mahan, E. C. (Coll. Health Science and Hosp., Univ. Kansas Medical Center, Kansas City, KS, 66103); Jewell, W. R. *Am Assoc Cancer Res* 19: 96; 1978. (no refs)

6505 **Cell Receptor Studies on Six Anaplastic Tumours of the Thyroid.** (Eng) Macaulay, R. A. (Dept. Forensic Medicine, Univ. Edinburgh, Edinburgh, Scotland); Dewar, A. E.; Langlands, A. O.; Stuart, A. E. *J Clin Pathol* 31(5): 461-468; 1978.

An attempt was made to distinguish malignant lymphoma from other thyroid tumors by examining suspensions of tumor cells for lymphocyte surface markers. The results were related with the ultrastructural appearance of the tumors, clinical extent of the disease, and response to radiotherapy. Cell suspensions were obtained from the anaplastic thyroid tumors of six patients (5 women, 1 man, aged 60-85). In five cases, many of the cells showed surface immuno-

globulin. Electron microscopy studies of three of these tumors were indicative of malignant lymphoma. In 2/5 cases, the patients had a history of previous thyroid disease. The single tumor that did not show surface immunoglobulin had an entirely different ultrastructure and was probably a carcinoma. This patient was the only one that did not achieve complete remission with radiotherapy, and she died from extensive local recurrence. It is concluded that receptor techniques are of value in distinguishing between malignant lymphoma and other anaplastic tumors of the thyroid, particularly when the results are correlated with histology. PATHOGENESIS

- 78-6506 Genetically Determined Sex-Reversal in 46,XY Humans.** (Eng) German, J. (New York Blood Center, 310 E. 67 St., New York, NY, 10021); Simpson, J. L.; Chaganti, R. S.; Summitt, R. L.; Reid, L. B.; Merkatz, I. R. *Science* 202(4363): 53-56; 1978.

Observations of one family that constitute strong evidence for the existence in humans of an X-borne gene that in mutant form results in sex-reversal in 46,XY individuals are reported. They also provide further insight into the genetic control of normal human gonadal differentiation. Affected were two sisters, their maternal aunt, and one first cousin from another maternal aunt. All four developed normally throughout childhood. At puberty, axillary and pubic hair developed normally, but breast development and menstruation had to be induced by appropriate hormones. None of the four displayed Turner's syndrome characteristics. Genitalia were unambiguously female, and uterus and fallopian tubes were normal at prepubertal age. Upon pelvic surgery (between age 19 and 29), however, the sisters were found to have bilateral streak gonads reminiscent of 45X gonadal dysgenesis. The cousins's gonads were grossly streaklike, but were proved to be bilateral gonadoblastomas. Pathology of an abdominal tumor removed from the aunt is unknown, but suspect. Chromosome studies of the three living women (the aunt died postoperatively) ruled strongly against mosaicism. X and Y chromosomes appeared normal in banding studies. The inability of the Y chromosome alone to initiate male differentiation of the embryo was ruled out, because three of the Y chromosomes came from different fathers. Therefore, it was hypothesized that some X-Y interaction is necessary for the initiation of male differentiation and that in these women the necessary X locus was mutant, perhaps transmitted as an X-linked recessive trait. In the absence of male differentiation and in the presence of only one X, the sexual differentiation resulting in streak gonads was like that seen in 45X gonadal dysgenesis. (27 refs)

- 78-6507 Uneven Geographical Distribution of 15;17-Translocation in Acute Promyelocytic Leukaemia (Letter to Editor).** (Eng) Teerenhovi, L. (Third Dept. Medicine, Univ. Helsinki, SF-00290 Helsinki 29, Finland); Borgstrom, G. H.; Mitelman, F.; Brandt, L.; Vuopio, P.; Timonen, T.; Almqvist, A.; de la Chapelle, A. *Lancet* 2(8093): 797; 1978.

In contrast to findings in Belgian and, perhaps, US patients, none of the nine Finnish and three Swedish patients with acute promyelocytic leukemia (APL) examined (comprising all cytogenetically analyzed cases from Finland and southern Sweden) had a 15;17-translocation. Apparently, there is a

striking difference in the geographical distribution of the chromosome anomaly in APL patients. (10 refs)

- 78-6508 Simultaneous Occurrence of Non-Hodgkin Lymphoma and Spontaneous Acute Granulocytic Leukemia.** (Eng) Youness, E. (Dept. Lab. Medicine, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave. Houston, TX, 77030); Ahearn, M. J.; Drewinko, B. *Am. Clin. Pathol.* 70(3): 415-420; 1978.

The second reported case of simultaneous non-Hodgkin lymphoma and spontaneous acute granulocytic leukemia occurred in a 67-yr-old Caucasian farmer. He had no remarkable family or medical history except for chronic exposure to some form of insecticide. The diagnoses of the two diseases were confirmed by examination of the patient's bone marrow and peripheral blood specimens at the light and electron microscopic level and by autopsy findings. Comparison of the patient with the previously reported patient (a woman) showed that both had no prior history of chemotherapy and/or radiotherapy, they were in their late 60's, they had relatively short histories of anemia and wt loss, and they had simultaneous involvement of lymphopoietic organs and peripheral blood. The woman had generalized lymphadenopathy and blast-containing Auer rods, but the man had lymphoid involvement confined to the liver, spleen, and bone marrow and his blasts did not show Auer rods. Chronic exposure to an unknown insecticide may have played a leukemogenic role in the latter. (32 refs)

- 78-6509 Probable Clonal Origin of Acute Myeloblastic Leukemia Following Radiation and Chemotherapy of Colon Cancer.** (Eng) Wiggans, R. G. (Dept. Medicine, Div. Medical Oncology, Georgetown Univ. Hosp., Vincent T. Lombardi Cancer Res. Center, Georgetown Univ. Washington, DC); Jacobson, R. J.; Fialkow, P. J.; Woolley, P. V.; Macdonald, J. S.; Schein, P. S. *Blood* 52(4): 659-663; 1978.

Acute myeloblastic leukemia (AML) developed in a 64-yr-old black woman after radiation and drug therapy for disseminated colon cancer. The occurrence and then progression of pulmonary metastases prompted two ⁶⁰Co-radiation treatments (3,500 and 4,200 rads) 3 and 1 yr before AML diagnosis respectively. She was also treated with cytotoxic drugs in the 2 yr prior to diagnosis, including intermittent courses of 5-fluorouracil throughout that time and, in the year preceding diagnosis, with 1-(2-chloroethyl)-3-(4-methylcyclohexyl)-1-nitrosourea (4 mo) and streptozotocin (3 wk). Approx

Amounts of B and A types of glucose-5-phosphate dehydrogenase were found in skin and cultured skin fibroblasts, only type B was detected in the abnormal WBC. In chromosome studies, cultured cells from normal tissues were normal, but all 90 unstimulated blood cells studied were missing approx two-thirds of the short arms of chromosome 12 (X,12p-). This abnormality was also detected in 18/24 unstimulated marrow cells. These data are consistent with a clonal origin of this leukemia. (23 refs)

78-6510 Multifocal Histogenesis of a Cystosarcoma Phyllodes. (Eng.) Salm, R. (Dept. Histopathology, Royal Postgraduate Medical Sch., Hammersmith Hosp., Duane Road, London W12 0HS, England). *J Clin Pathol* 31(9): 897-903; 1978.

An unusual multifocal cystosarcoma phyllodes (CSP) occurred in a 50-yr-old woman. The CSP presented as a small, well-circumscribed tumor mass, and it was associated with two separate neoplastic lesions that arose sequentially in two separate parts of the mammary disk. Microscopically, the tumor appeared to have been enlarging by the formation of isolated minute tumor nodules within the adjacent normal breast tissue. This represents a third mechanism by which CSP may arise, the other and more common modes being expansion in situ and extension of tumor projections from the periphery. (6 refs)

78-6511 Soft Tissue Sarcomas in the Cat. (Eng.) Brown, N. O. (Donaldson-Atwood Cancer Clinic, Animal Medical Center, 510 E. 62nd St., New York, NY, 10021); Malik, A. K.; Mooney, S.; Hayes, A.; Harvey, H. J.; Ewen, E. G. *J Am Vet Med Assoc* 173(6): 744-749; 1978.

A retrospective survey was made of the soft tissue sarcomas found in 23 cats at an animal medical center from 1971 to 1976. The nature of the tumors was variable. All tumors tended to develop in older cats and in various locations, although most were on the extremities. Diagnosis was made upon biopsy. No feline leukemia virus was detected in the 13 cats tested. (10 refs)

78-6512 Connection Between Accidental Trauma and Course of Malignant Melanoma of the Skin. (Ger.) Wozniak, K. D. (Universitäts-Hautklinik, Ernst-Reuter-Strasse 5/8, DDR-402 Halle [S], E. Germany). *Dermatosen Beruf Umwelt* 26(5): 166-168; 1978.

The use of malignant melanoma that may have been accelerated into rapid metastasis by trauma is described. A 38-yr-old man who had a lentil-sized nevus above his left knee for as long as he could remember presented with painful lymph node swelling in the left groin. He reported that the

nevus had been growing for 6 mo. At presentation it was cherry-sized, half-spherical, gray-black, tender, and eroded. After this tumor was removed it was identified as a melanocytoblastoma, partly round-cell and partly spindle cell in composition. The inguinal lymph nodes were also removed. They had the same histology as the tumor. The patient was wounded in the area of the nevus 4 mo before presentation; the wound caused erosion of the nevus. An inflammatory reaction resulted and lymphangitis followed soon after. The patient was symptom-free for 3 mo after treatment, but then neurological symptoms appeared. In spite of intensive therapy, the patient died of heart failure. At autopsy, generalized metastases of the melanoma were found in the iliac artery and aorta, liver, and spleen. Although trauma is no longer considered a cause of melanoma, trauma to a nevus that has begun to undergo malignant transformation may accelerate the course of the disease, as suggested by this case. (24 refs)

78-6513 Malignant Lymphoproliferative Disorders in Chronic Liver Disease. Report of Four Cases and Review of the Literature. (Eng.) Naparstek, J. (Dept. Medicine, Hadassah Univ. Hosp., Jerusalem, Israel); Elia-kim, M. *Am J Dig Dis* 23(10): 887-892; 1978.

The case reports of four patients (3 men, 1 woman 54-61 yr old) with chronic liver disease who later developed lymphoma are given, and the related literature is reviewed. Three of the patients had nonalcoholic cirrhosis and one had chronic cholangitis. Non-Hodgkin's lymphoma developed long after the presence of liver disease had been established in three patients; the fourth died of hepatic coma, and Hodgkin's disease was discovered incidentally at autopsy. No drugs could be implicated in the appearance of the liver disease or the lymphoma. The findings of these four cases within a relatively short period suggests that the association between the two conditions is not incidental. A review of the literature yielded 40 additional cases. In many, lymphoma complicated long chronic liver disease; in others, however, liver disease was secondary to hepatitis B infection or to treatment of lymphoma. Among the several mechanisms that may be operative in the pathogenesis of lymphoma in patients with liver cirrhosis, chronic antigenic stimulation, the presence of hepatitis B surface antigen, and immunosuppressive therapy seem to be the most important. (44 refs)

78-6514 An Unusual Case of Bence-Jones Myeloma with Unreleased γ Heavy Chains in the Cytoplasm of the Myeloma Cells: A Close Relationship Between Bence-Jones Myeloma and Nonsecretory Myeloma. (Jpn) Kanoh, T. (First Div., Dept Internal Medicine, Faculty of Medicine, Kyoto Univ., Kyoto, Japan); Dohmae, N.; Uchino, H.; Sugimoto, C.; Shimada, T. *Acta Haematol Jpn* 41(5): 938-944; 1978.

A case of Bence Jones (K) partially nonsecretory myeloma with unreleased γ heavy chains in the cytoplasm of the myeloma cells is presented, and the close relationship between Bence Jones myeloma and nonsecretory myeloma is discussed. Bence Jones myeloma arises from one of the following mechanisms, most of which are common to nonsecretory myeloma: (1) loss of the capacity to synthesize heavy chains (Bence Jones myeloma without heavy-chain synthesis); (2) loss of the capacity to secrete whole molecules of immunoglobulins, with secretion of light chains only (Bence Jones myeloma with heavy-chain synthesis); and (3) secretion of immunoglobulins with an abnormal heavy or light chain and their rapid extracellular degradation (Bence Jones myeloma without detectable immunoglobulin synthesis). The pathogenesis of the present case may be due to mechanism 2. The characteristic picture of myeloma cells filled with numerous Russell bodies in the present case might be related to the presence of unreleased γ heavy chains in the cytoplasm. (19 refs)

78-6515 Radium-Induced Cancer: Excessive Radium Dosage (Meeting Abstract). (Eng) Applebaum, E. L. (Glencoe, IL). *Otolaryngology* 86(4): 188-189; 1978. (no refs)

78-6516 Tumor and Tumor-like Lesions of Perilimbal Conjunctiva in Laboratory Dogs. (Eng) Hargis, A. M. (Collaborative Radiological Health Lab., Dept. Pathology, Colorado State Univ., Fort Collins, CO, 80523); Lee, A. C.; Thomassen, R. W. *J Am Vet Med Assoc* 173(9): 1185-1190; 1978.

Among 1,680 research colony beagles, proliferative and neoplastic lesions developed in the nasal or temporal limbal conjunctiva of 8 male and 6 female dogs. The mean age at observation was 5.2 yr. Acanthosis and squamous cell carcinoma of the conjunctival epithelium to vascular ectasia, hemangioma, and invasive hemangiosarcoma of the underlying lamina propria were seen. The dogs had been kept in a sunny, relatively high-altitude (1,500 m), smog-free area, suggesting that exposure to solar radiation may have been involved in tumor development. (19 refs)

78-6517 Cerebellar Medulloblastoma: An Analysis of Four Cases of Extraneural Metastasis. (Eng) Schnitzler, E. R. (Dept. Neurology, Univ. Wisconsin, 1300 University Ave., Madison, WI, 53706); Richards, M. J.; Chun, R. W. *Am J Dis Child* 132(10): 1004-1008; 1978.

The cases of 4/28 medulloblastoma patients who developed extraneural metastases are reviewed, and their clinical features are compared with those of the 24 patients without metastases. Suboccipital craniectomy, radiation therapy, and

patient longevity were not well-correlated with metastasis. However, subarachnoid tumor spread was a consistent cursor (4/4 patients with metastasis vs 7/24 without). A triculoatrial shunt may have been a factor in one patient. A serious infection that preceded diffuse metastases may have been a factor in another. Two of the four patients with metastases had the desmoplastic variety of medulloblastoma, only 1/24 without metastases had this variant. Identification of the medulloblastoma patient with an increased risk of extraneural metastasis is difficult but it has practical implications, since recent studies indicate that this metastasis is sensitive to chemotherapy. 78-6518 Linkage Study in a Kindred with Multiple Endocrine Neoplasia (MEN 41) (Meeting Abstract). (Eng) Forster, C. J. (Queen's Univ., Toronto, Ontario, Canada); Sears, E.; Ghent, W.; Falk, J.; Goodall Partington, M. W.; Simpson, N. E. *Can J Genet Cytol* 20: 443; 1978. (no refs)

78-6519 Squamous Cell Carcinoma Arising in a Meningiomyelocoele. (Eng) Saksun, J. M. (Div. I Pathology, Dept. Medicine, Wellesley Hosp., 160 Wellesley St., E., Toronto, Ontario M4Y 1J3, Canada); Fisher, B. *Can Med Assoc J* 119(7): 739-741; 1978.

A squamous cell carcinoma arose in a lumbosacral meningiomyelocoele of a 25-yr-old man. Only two similar cases were found in the literature. Neoplastic change in untreated meningiomyelocoeles is possible after years of mechanical irritation due to braces and chronic bacterial infection. (28 refs)

78-6520 Pathogenesis of Attic Cholesteatomas. (Eng) Sade, J. (Meir General Hosp., Kfar Saba, Israel). *J R Soc Med* 71(10): 716-732; 1978.

To determine the mode of genesis of attic cholesteatomas (AC), 22 of these tumors were investigated in situ and in toto. They were all epidermoid cysts of elaborate cellular organization, 18 of which were situated medial to the ossicular chain. This site makes self-cleansing difficult, producing secondary infection. Three AC had no connection with the external ear canal. However, whether or not AC communicate with the external canal, they have a lining that often has mixed epithelium: stratified squamous epithelium (EC) synthesizing keratin and respiratory epithelium producing mucus. This shows that a metaplastic process is involved, at least to some degree. Therefore, AC are epidermoid cysts that originate primarily in the attic from epithelial cells that metaplastic mature into keratinizing epithelium. They often present themselves secondarily in the external canal as a perforated epidermoid cyst. The favored etiology of an invasive retraction from the external ear is difficult to accept in view of the

tact inhibition of the SE or the invariable outward migration of stratified SE from the edges of retraction pockets as well as from cholesteatoma perforations. Also, there is no documentation of an evolution of AC from preexisting perforations or from marginal perforations. (47 refs)

78-6521 Intranasal Tumor of the Ethmoid Olfactory Mucosa in Sheep. (Eng) Yonemichi, H. Takikawa Animal Husbandry Experimental Station, Hokkaido, Takikawa 073, Japan; Ohgi, T.; Fujimoto, Y.; Okada, T.; Onuma, M.; Mikami, T. *Am J Vet Res* 39(10): 1599-1606; 1978.

Intranasal tumors (papillary adenomas or adenocarcinomas) of the ethmoid olfactory mucosa of sheep were investigated by light and electron microscopy. The fine structure of the tumor cells was characterized by the presence of numerous secretory granules. Viral particles that were morphologically similar to a visna-maedi virus were detected in all tumor tissues and in 3/4 cultures examined. The particles [93-97 nanometers (nm)] had an eccentrically located electron-dense core (47 nm), often surrounded by a single (intermediate) membrane; these particles also had numerous spikes (9 nm) on their surfaces. There were no viral particles in the lung of sheep with pneumonia or in the normal olfactory mucosa of two control sheep. RNA-dependent DNA polymerase (DDP) activities in the tumor tissues or in cultured tumor cells were greater than those in normal intranasal tissues or cultured cells from the choroid plexus. Viral particles similar to herpesvirus were also detected in one culture, and particles of a paravaccinia type were found in another. (28 refs)

78-6522 Familial Medullary Thyroid Carcinoma. (Eng) Hillyard, C. J. (Dept. Surgery, Royal Postgraduate Medical School, Hammersmith Hosp., Duane Road, London W12 0HS, England); Evans, I. M.; Hill, P. A.; Taylor, J. *Lancet* 1(8072): 1009-1011; 1978.

Twenty-one relatives of a 14-yr-old girl with medullary thyroid carcinoma (MCT) were screened by the plasma calcitonin assay before and after alcohol provocation. The patient's mother and two siblings had raised basal levels, and the diagnosis of MCT was confirmed at surgery; their calcitonin levels became undetectable after total thyroidectomy. Only 1/3 had a palpable thyroid mass. Three more distant relatives had detectable calcitonin levels after alcohol stimulation, and they are being rescreened at regular intervals. Cervical lymph node metastases were found in the index patient 1 mo after total thyroidectomy. Her current calcitonin level is now 36.8 pg/liter. (9 refs)

78-6523 Total Thyroidectomy: The Indications and Results of 630 Cases. (Eng) Katz, A. D. (8733 Beverly

Blvd., Los Angeles, CA, 90048); Bronson, D. *Am J Surg* 136(4): 450-454; 1978.

Indications for total thyroidectomy are illustrated in a series of 630 patients (499 females, 131 males aged 7-83 yr) in whom this operation was performed during 1958-1978 in Los Angeles County. The patients were divided into three groups: (I) 121 with Grave's disease; (II) 133 with a history of childhood head, neck, and thorax irradiation and a cold thyroid nodule; and (III) 396 with a dominant cold thyroid nodule suspected of being a carcinoma. The total cancer incidence was 193/630 patients: 183 had papillary follicular carcinoma, 4 medullary carcinoma, 5 anaplastic or small cell carcinoma and 1 reticulum cell sarcoma. Group I patients had a 5% malignancy rate, Group II a 42.5% rate, and Group III a 35% rate. Concerning Group II patients, available data indicate that at least 2% of individuals whose thyroids were exposed to 300 rads of x-rays will develop thyroid cancer within 25 yr and that 9% will have benign nodules. Irradiation of thymolymphatic tissue in the head, neck, and thorax might result in changes in lymphoid elements that subsequently reach the thyroid gland. Lymphoid elements are far more vulnerable to radiation-induced changes than thyroidal epithelium. In most of the 113 Group II patients, both lobes of the thyroid were grossly and microscopically abnormal (follicular and Hurthle cell adenomas, multicentric carcinomas, and thyroiditis). (25 refs)

78-6524 Synovial Sarcoma of the Neck. (Ita) Berton, F. (Servizio di anatomia ed istologia patologica, Ospedale Marcello Malpighi di Bologna, Bologna, Italy); Bacchini, P. *Pathologica* 70(1005/1006): 409-418; 1978.

The case of a 42-yr-old woman with synovial sarcoma of the neck is reported. The patient had symptoms of pain in the neck region, swelling, and hoarseness. Examination of the larynx revealed a polypous neoplasm on the posterior and lateral walls of the pharynx. A biopsy was performed, and a diagnosis of synovial sarcoma was made. The patient underwent a partial pharyngectomy and a total laryngectomy. No evidence of metastases to the cervical lymph nodes was found. Microscopically, fused cells were seen with voluminous nuclei and a granular-eosinophilic cytoplasm. The nuclei were polydimensional, with indented and jagged membranes. Histologically, the neoplasm was composed of two components: epitheliallike and mesenchymal. The epithelial-like components (PAS- and Alcian-positive) formed pseudoglandular formations. The mesenchymal component was pressed between these formations and was rarely PAS- or Alcian-positive. The histological aspects confirmed the diagnosis. (15 refs)

78-6525 Mammary Gland Hyperplastic Alveolar Nodulogenesis in the LEW/Mai Rat in Relation to Mitotic Activity, Estrous Cycle Status, and Age. (Eng)

Purnell, D. M. (Dept. Pathology, Sch. Medicine, Univ. Maryland, 660 W. Redwood St., Baltimore, MD, 21201); Stowers, D. J. *J Natl Cancer Inst* 61(5): 1339-1346; 1978.

The genesis of spontaneous mammary hyperplastic alveolar nodules (HAN) was studied in nulliparous female LEW/Mai rats in relation to age, estrous cycle status, and mammary gland mitotic activity. Mitotic activity in the contralateral mammary gland rose almost linearly from 30 to 108 days of age and then fell progressively, although it remained significantly higher than the activity in mammary glands of rats < 100 days old. Mitotic activity was nonrandomly distributed in the mammary glands of young pubertal rats in contrast to that in glands of prepubertal rats and in rats in persistent estrus. The percentage of rats with HAN as well as the incidence of HAN in the inguinal mammary gland increased progressively with age. At 150 days of age, 12.5% of the rats had 1-5 HAN/inguinal mammary gland; by 183 days, 18.5% had 1-19 HAN/gland; and by 215 days, 91.7% had 3-44 HAN/gland. HAN were more common near the nipple than in other regions of the mammary gland. They appeared only in rats in persistent vaginal estrus, and they were more frequent in rats that displayed this condition for the longest period of time. Rats with HAN also had significantly increased pituitary wts. These findings suggest that hormone imbalance may be an important etiologic factor in the genesis of spontaneous HAN in rats. (20 refs)

78-6526 Phagocytosis of Tumor Cells by Murine Kupffer Cells In Vivo and In the Perfused Mouse Liver. (Eng) Roos, E. (Div. Cell Biology, Antoni van Leeuwenhoekhuis, Netherlands Cancer Inst., Sarphatistraat 108, Amsterdam, Netherlands); Dingemans, K. P. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 216-224; 1977.

The behavior of Kupffer cells toward several tumor cell lines (mammary adenocarcinomas TA3/Ha and TA3/St, melanoma B16, lymphosarcoma MB VI A, and thymic leukemias GRSL-18 and GRSL-19) was studied after in vivo injection of the tumor cells in the portal system of mice or addition of these cells to a synthetic medium that perfused an isolated mouse liver. Within 30 min after their arrival into the liver, TA3 and B16 cells were partly or completely surrounded by thin, electron-lucent cell processes of Kupffer cells. Micrographs suggest that the tumor cells were surrounded by a thin rim of Kupffer cell cytoplasm that subsequently contracted to enclose part or all of the tumor cell. A dense material, probably containing lysosomal enzymes, was then released around the enclosed tumor cell and it was subsequently degenerated. These observations strongly suggest that the cells were phagocytized. For the TA3 and B16 cells, there was no difference in the percentage of partially or completely surrounded tumor cells after 30, 60, 90 or 120 min. The average percentage of the cell surface covered by the Kupffer cells

was similar in all experiments with one tumor cell line also did not tend to increase with time. MB VI A and GRSL cells were little affected by the Kupffer cells. The data from the perfusion and in vivo experiments were similar (refs)

78-6527 Effect of Parity on Recovery of Inapparent Nodule-transformed Mammary Gland Cells In Vivo. (Eng) DeOme, K. B. (Dept. Zoology, Univ. California Berkeley, CA, 94720); Miyamoto, M. J.; Osborn, R. C.; Gorman, R. C.; Lum, K. *Cancer Res* 38(11, part 2): 4050-4054; 1978.

Inapparent nodule-transformed cells were recovered from late-pregnant BALB/cfC3H mice (5 first-pregnancy females 4 mo old, 5 multiparous females 6-7 mo old) by a cell-coculture technique, aliquots of 100,000 viable cells in 0.1 ml media were injected into the gland-free mammary fat pad of 3-wk-old syngeneic hosts, and the emergence of typical nodule outgrowths (LA's) was determined. Recovery of LA's indicated the presence of nodule-transformed cells in the inoculum. The results were compared with those derived previously from virgin BALB/cfC3H mice. The percentage of LA-type outgrowths (LS's, nodule-ductal outgrowths, and nodule-tumor outgrowths) derived from both donor groups was high: 63% and 45% for those aged 4 and 6-7 mo, respectively. There was no correlation between the percentage of LA's and donor age or number of litters born. Virgin mice of the same ages averaged 11% LA's. LA's were recovered from all 10 of the parous donors, vs only 8/12 of the virgin donors. Hyperplastic alveolar nodules (HAN) and tumors were not encountered in virgins < 8-9 mo old, whereas 36% of the parous females 4-5 mo old had overt HAN and 3.6% had tumors, and 73% of the parous females 8-9 mo old had overt HAN and 73% had tumors. The incidence of overt lesions was only 40% in virgins aged 12-14 mo. The data suggest that parity significantly increases the number of nodule-transformed cells in donor tissue, decreases the time required for the emergence of nodules and tumors, and increases the number of overt nodules and tumors. (7 refs)

78-6528 The Respiratory Epithelium. III. Histogenesis of Epidermoid Metaplasia and Carcinoma In Situ in the Human. (Eng) Trump, B. F. (Dept. Pathology, Univ. Maryland Sch. Medicine, 31 S. Greene St., Baltimore, MD, 21201); McDowell, E. M.; Glavin, F.; Barrett, L. A.; Becci, P. J.; Schurch, W.; Kaiser, H. E.; Harris, C. C. *J Natl Cancer Inst* 61(2): 563-575; 1978.

In an effort to test the hypothesis that epidermoid metaplasia (EMP) in the bronchial epithelium can result from direct conversion of columnar mucous cells to keratinizing epidermoid cells, bronchial specimens of 100 patients with and without lung cancer were studied by light and electron microscopy. Of the 71 lung cancer patients, 15 showed focal

P. The metaplastic epithelium was characteristically composed of basal cells overlaid by small mucous granule cells (SMGC) that became progressively flattened toward the luminal surface. Ciliated cells were absent. EMP showing differentiation was seen in only two specimens, both from cancer patients. Epithelium showing mucous goblet cell hyperplasia and ciliated epithelium underwent abrupt transition to that of noncornifying metaplastic epithelium. Mucous goblet cell hyperplasia was seen in more than half of the specimens; a pattern of stratification was noted in some areas in one-third of these hyperplasia specimens. Layers of SMGC overlaid a row of basal cells, and the surface layer consisted of cuboidal mucous goblet cells and/or SMGC. Staining of metaplastic cells produced patterns similar to those of mucous cells in mucous goblet cells. Electron microscopy further confirmed the mucous nature of these cell types. This study emphasizes the differentiation potentialities of mucous cells that can divide and undergo goblet cell hyperplasia and EMP. It is suggested that EMP and carcinoma in situ can result from the conversion of mucous cells. (73 refs)

6529 **Carcinoma of the Lung in a Drywall Taping Worker. Report of a Case.** (Eng) Fischbein, A. (Environmental Sciences Lab., Dept. Community Medicine, Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. and 100th St., New York, NY, 10029); Langer, A. M.; Suzuki, Y.; Selikoff, I. J. *Toxicol Lett* 2(4): 231-236; 1978.

Case of lung cancer in a 57-yr-old man who had been a heavy smoker and a drywall taping worker for 25 yr is reported. Histologically, the tumor was a well-differentiated squamous cell carcinoma. Congestion of the pulmonary parenchyma, edema, bronchopneumonia, and pulmonary fibrosis were also present. Numerous particles--sheet silicates, diatom fragments, chrysotile asbestos fibrils, and unidentified crystalline fibers--were observed throughout the lung tissue. The size of these particles was $< 1 \mu\text{m}$ in greatest dimension. This case illustrates the importance of tissue analysis in the evaluation of dust disease of the lung. (7 refs)

6530 **Giant Cell Transformation: Cerebrohepatorenal Syndrome.** (Eng) Carlson, B. R. (Dept. Pathology, Children's Medical Center, 1935 Amelia, Dallas, TX, 75235); Weinberg, A. G. *Arch Pathol Lab Med* 102(11): 596-599; 1978.

A male infant with cerebrohepatorenal syndrome of Zellweger was found, upon liver biopsy performed at 6.5 wk of age, to have extensive hepatic giant cell transformation. In addition to features atypical of the early phase of the syndrome there was widespread enlargement and multinucleation of hepatocytes. Upon autopsy at 16 wk, the liver showed early cirrhosis and rare giant cells. Zellweger's syndrome may represent another form of hepatic insult that may induce giant cell transformation. (19 refs)

78-6531 **Hepatoma Development During Long Term Follow-up Period of Liver Cirrhosis.** (Eng) Kobayashi, K. (First Dept. Internal Medicine, Sch. Medicine, Kanazawa Univ., Kanazawa, Japan); Kumagai, M.; Kameda, S.; Sugimoto, T.; Suzuki, K.; Nishimura, K.; Kato, Y.; Sugioka, G.; Hattori, N. *Acta Hepatogastroenterol (Stuttg)* 25(5): 344-349; 1978.

The relationship of hepatoma to liver cirrhosis was investigated, based on long-term (> 3 yr) follow-up studies of 20 Japanese patients with liver cirrhosis. Hepatoma was found at autopsy in 10/20 patients, all of whom had mixed-type cirrhosis. In the nonhepatoma group, two had micronodular cirrhosis and eight had the mixed type. The mean follow-up in the hepatoma and nonhepatoma patients was 5.5 and 5.0 yr, respectively. There were no heavy drinkers among the hepatoma patients, vs three in the nonhepatoma group. Blood samples were analyzed for hepatitis B surface antigen (HBsAg) and α -fetoprotein (FP) by radioimmunoassay, and localization and distribution patterns of HBsAg in the liver were determined by direct immunofluorescence and orcein staining. Six of the eight hepatoma patients tested were positive for HBsAg, vs 2/10 nonhepatoma patients. FP levels $> 20 \mu\text{g/ml}$ were detected in 6/8 hepatoma patients tested, and in four of these patients they were $> 300 \mu\text{g/ml}$. These results indicate that HBsAg-positive liver cirrhosis of the mixed type is closely related to hepatoma development in Japan. (12 refs)

78-6532 **Ultrastructural Features of Renal Carcinoma Cells.** (Rus) Dikshtein, E. A. (Dept. Pathological Anatomy, M. Gor'kii Donetsk Medical Inst., Donetsk, USSR); Vlodavskii, E. A.; Shevchenko, N. I.; Miima, J. G.; Merezko, V. A. *Arkiv Patol* 40(8): 10-16; 1978.

The ultrastructure of three renal cell carcinomas was studied. Two basic cell types were found. Clear cells, which predominated in these carcinomas, were characterized by a cytoplasm rich in lipid vacuoles and glycogen granules. Dark cells, which were scarce, contained small amounts of fat and glycogen but had well-developed mitochondria and other organelles. Both types of cells contained microvilli on the cell surface, desmosomes and interdigitations in the region of the cell contacts, and channels between the tumor cells. These features suggest that clear and dark cells have a common origin in the epithelium of the proximal tubules. (6 refs)

78-6533 **Mixed Endocrine Gastric Tumors Associated with Hypergastrinemia of Antral Origin.** (Eng) Larsson, L. I. (Inst. Medical Biochemistry, Univ. Aarhus, DK-8000 Aarhus, Denmark); Rehfeld, J. F.; Stockbrugger, R.; Blohme, G.; Schoon, I. M.; Lundqvist, G.; Kindblom, L. G.; Save-Soderberg, J.; Grimelius, L.; Olbe, L. *Am J Pathol* 93(1): 53-68; 1978.

Hypergastrinemia of antral origin associated with multiple mixed endocrine tumors of the gastric corpus mucosa occurred in a 57-yr-old diabetic woman. A screening test revealed serum gastrin levels of 4,000-5,000 picograms (pg)/ml (normal levels are < 100 pg/ml), and a pentagastrin test revealed achlorhydria. Upon gastroscopy, approx 20 polypous lesions were detected in the corpus mucosa. Following gastrectomy, serum gastrin levels decreased to < 10 pg/ml. Most (70%-80%) of the tumor cells were of the endocrine cell (so-called ECL cell) type, but enterochromaffin cells of various subtypes and agranular cells were also found. The tumors were locally invasive into the walls of submucosal blood vessels. The surrounding mucosa showed severe atrophic gastritis with intestinalization and contained numerous goblet cells, enterochromaffin cells, and cholecystokinin cells. The latter do not occur in normal oxyntic mucosa. Their presence in intestinalized gastric epithelium suggests that intestinalization also is associated with changes in endocrine cell populations. Gastrin exerts a trophic action on ECL cells. It is speculated that the primary lesion was achlorhydria; the subsequently raised serum gastrin levels, caused by decreased acid feedback inhibition, may have been instrumental in bringing about the hyperplasia and neoplasia of the ECL cells. (30 refs)

- 78-6534 **Adenocarcinoma of the Stomach with Common Variable Immunodeficiency Syndrome.** (Eng) Battle, W. M. (Section Gastroenterology, Dept. Medicine, Univ. Pennsylvania Hosp. and Sch. Medicine, 3600 Spruce St., Philadelphia, PA, 19104); Brooks, F. P. *Arch Intern Med* 138(11): 1682-1684; 1978.

Gastric adenocarcinomas developed as a late complication of the common variable immunodeficiency (CVI) syndrome in a man and a woman who were followed since age 27 and 30 yr, respectively. The syndrome was diagnosed on the basis of onset of disease in adolescence, no family history of increased susceptibility to infection, and little or no circulating IgG, IgA, or IgM. Atrophic gastritis and pernicious anemia were present in both patients. The anemia was characteristic of the CVI syndrome, with a defect in absorption of vitamin B₁₂ and a lack of correction of the Shilling test after administration of intrinsic factor. In both cases, serum gastrin levels remained normal. Adenocarcinoma of the stomach was the most common epithelial tumor in a previous series of malignancies associated with the CVI syndrome. - 78-6535 **Relationship Between Chronic Schistosomiasis Japonica and Carcinoma of the Large Intestine: Studies on 12 Cases of Adenocarcinoma of Large Intestine Associated with Eggs of *Schistosoma japonicum*.** (Jpn) Inoguchi, T. (First Dept. Surgery, Kurume Univ. Sch. Medicine, Kurume, Japan); Adachi, T.; Yamauchi, Y.; Isomoto, H.; Takamori, K.; Shinohara, M. *Igaku Kenkyu* 48(2): 93-100; 1978.

The relationship between chronic infection by *Schistosoma japonicum* and carcinoma of the large intestine was investigated. In 12 of 381 patients resected for colonic cancer/cancer/parasite association was demonstrated histologically mainly in the rectum and colon, with the stromal reaction in the mucosal or submucosal layer. However, a causal relationship could not be proven. (42 refs)

- 78-6536 **Histogenesis of Malignant Transformation of the Colonic Epithelium. A Detailed Study of Semi-thin Sections.** (Eng) Mughal, S. (Dept. Histopathology, Westminster Medical Sch., London, England); Filipe, M. *Acta Gastroenterol Belg* 41(5/6): 215-225; 1978.

The histogenesis of colonic cancer was studied using semithin (1 micron) resin sections of normal mucosa from 6 patients without gastrointestinal disease, adenomatous polyps and/or carcinomas from 11 patients with familial polyposis coli (FPC), polyps from 8 patients without FPC, and 5 adenocarcinomas. For light microscopy, the sections were stained with toluidine blue (TB), periodic acid-silver methenamine (PASM), PAS, high iron diamine (HID), and alcian blue (AB). The semithin sections revealed the gradations of epithelial atypia from normal mucosa through adenoma to carcinoma to the same degree as did electron microscopy (EM). Goblet cell increases associated with changes in mucin secretory products were shown by PASM. Vesiculated and electron dense bodies were visible with PASM and PAS staining and undifferentiated cells were easily identified with TB and PASM. AB and HID highlighted variations in mucous secretions in apparently normal mucosa adjacent to neoplastic growths. Other features indicative of epithelial dysplasia were alterations in the basement cell membrane and microvilli and nuclear atypia. In FPC, the changes were more severe in the large polyps of the left colon and also in the polyps of the carcinoma patients. The advantages of semithin sections over EM and routine histology in detecting early cancer are discussed. (12 refs)

- 78-6537 **Development of Cancer in Ulcerative Colitis.** (Swe) Fredlund, P. (Kirurgiska kliniken, Lasarettet, S-221 85 Lund, Sweden); Hoevels, J.; Petersson, B. G. Schain, M. *Lakartidningen* 75(40): 3539-3542; 1978.

Four patients (two men, two women, aged 29-48 yr) with ulcerative colitis developed colonic tumors. At surgery, two of the tumors were diagnosed as carcinomas and two as adenocarcinomas. Three patients also had peritoneal carcinomatosis. The interval between the diagnosis of ulcerative colitis and that of the colonic tumor was 12-20 yr in three cases, and approx 1 yr in the fourth. The incidence of colorectal cancer in ulcerative colitis is highest in the distal segment of the intestine. These cases confirm earlier observations on the increased incidence of colonic cancer in ulcerative colitis patients. (18 refs)

6538 Heritable Colon Cancer and Solitary Adenomatous Polyps. (Eng) Lynch, P. (Dept. Preventive Medicine, Creighton Univ., Omaha, NB); Lynch H.; Harris, J.; Guirgis, H. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1573-1589; 1978.

Study was made of a large cancer-prone kindred characterized by a wide variation in age of onset of colon cancer and either a total lack or sporadic distribution of adenomatous polyps in family members who developed colon cancer. Of approx 230 members in this kindred, 32 members have reportedly developed colonic and other gastrointestinal cancers. A striking trait expressed by this kindred is the inordinately high number of primary carcinomas occurring at the right colon. Among the 24 patients whose tumor sites have been documented, the cecum was involved in 16 cases, the ascending colon in 2, and the transverse colon in 4; only 2/24 had cancer at only the descending or rectosigmoid colon. The incidence of patients affected at the right colon is significantly greater than the highest reported figure for the general population. Solitary adenomatous polyps were found in 13 colon cancer patients, but 7 had no polyps. The prevalence of synchronous and metachronous colon cancers was approx 50%, with additional primary cancers arising after segmental colectomy. The lack of an association between polyps and cancer in this kindred brings into question the role of adenomatous polyps in malignant transformation. (19 refs)

6539 Histogenesis of Cloacogenic Carcinoma: Fine Structure of Anal Transitional Epithelium and Cloacogenic Carcinoma. (Eng) Gillespie, J. J. (Dept. Anatomic Pathology, Indiana Univ. Sch. Medicine, 1100 W. Michigan St., Indianapolis, IN, 46202); MacKay, B. *Hum Pathol* 9(5): 579-587; 1978.

The fine structural morphology of the anal transitional zone is described, and the ultrastructure of the two principal variants of cloacogenic carcinoma is presented. The descriptions are based on histologic and electron microscopic evaluation of eight cases of cloacogenic carcinoma (6 women, 2 men, 40-70 yr old) and tissue from four normal anorectal junctions. Anal transitional epithelium is not highly specialized and incorporates features of both urothelium and squamous epithelium; slight urothelial differentiation is probably vestigial. The transitional variant of cloacogenic carcinoma contained clusters of small vesicles and Golgi complexes, indicating partial differentiation. Histologically, the transitional variants resembled urothelial carcinoma but could be distinguished from it by numerous, well-formed desmosomes, frequent vil-

lous projections, and a distinctly elongated form. The pleomorphic and basaloid variants differed from the transitional type chiefly in their relative lack of differentiation. The basaloid tumors resembled cutaneous basal cell carcinoma morphologically and probably represent undifferentiated basal cells originating within the basal layer of anal transitional epithelium. The cloacogenic basaloid tumor is highly metastatic. The observation of features of both urothelial and squamous structure in the transitional variant confirms that it is derived from the anal transitional zone, which also contains features of both structures. (21 refs)

78-6540 Ovarian Fibromata in Four Successive Generations. (Eng) Dumont-Herskowitz, R. A. (New England Medical Center Hosp., 171 Harrison Ave., Boston, MA, 02111); Safaii, H. S.; Senior, B. *J Pediatr* 93(4): 621-624; 1978.

Brief case reports are given for six ovarian fibroma patients from four generations of the same family. In two patients (21 and 42 yr old), the tumors were unsuspected until hysterectomies had been done because of uterine fibroids. In the remaining four patients (3-16 yr old), the tumors were large, multinodular, and calcified and were discovered before menarche. The tumors were bilateral in three subjects. No endocrine effects could be ascribed to any of the tumors. The distribution of ovarian fibromas in this family was very different from that usually observed. The tumors typically occur in an older age group and after menopause. They are multiple or bilateral in only 10% of the patients and calcified in only 8.5%. Many and possibly all female subjects, including adolescents, who suffer from the basal cell nevus syndrome have ovarian fibromas that are characteristically multinodular and calcified, but none of the patients in this family had any signs of this syndrome. The disorder in this family followed a dominant mode of transmission. The pattern was consistent with either autosomal sex-limited or X-linked sex-limited inheritance. (10 refs)

78-6541 Characteristic Features of Hormonal Balance in Patients with Uterine Myoma. (Rus) Arakelian, A. B. (Dept. Obstetrics and Gynecology, Central Inst. Advanced Training Physicians, Moscow, USSR); Bakuleva, L. P. *Sov Med* (8): 140-144; 1978.

Changes in luteinizing hormone (LH), follicle-stimulating hormone (FSH), and somatotrophic hormone (STH) levels were studied in 35 patients with uterine myoma (26 were 24-40 yr old, 9 were 40-45 yr old). On the basis of rectal temperature, 14 patients had a normal biphasic menstrual

cycle, 13 had a reduced second stage of the cycle (duration of the follicular phase was 19 days, duration of the luteinic phase was 8 days), and 8 patients had a monophasic basal temperature. In all the patients, there was no correlation between the peaks of LH and FSH, and there were additional peaks of LH and FSH during the first and second phases of the menstrual cycle. The patients with a deficient luteinic phase and an anovular menstrual cycle had a significantly decreased basal level of LH and FSH. All the patients had mildly decreased levels of STH. Fourteen patients had internal endometriosis, and a retrospective analysis revealed that these patients underwent (on av) 3.13 abortions, compared with 1.64 abortions in the patients without endometriosis. EPIDEMIOLOGY AND BIOMETRY

543 **Pre- and Postmenopausal Breast Cancer: Differences in Risk Factors.** (Eng) Vakil, D. V. (Dept. Preventive Medicine and Biostatistics, Div. Community Health, Univ. Toronto, Toronto, Ontario, Canada); Goss, R. W. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1539-1550; 1978.

Because of the possibility that pre- and postmenopausal breast cancer represent two disease processes with different etiologies, an attempt was made to identify risk factors that differ between early- and late-onset breast cancer patients. A total of 170 former breast cancer patients were identified in the Toronto General Hospital tumor registry for 1960-1971. Information of genetic, epidemiological, and pathological importance was elicited in an interview questionnaire administered to all 170 women. Results of the survey revealed that 61 patients were premenopausal and 109 were postmenopausal at the time of diagnosis. Analysis of risk factors revealed that high socioeconomic status and early age at menarche were important in the development of premenopausal breast cancer. Nulliparity, age at first pregnancy, and weight-height index were more important in the development of postmenopausal breast cancer. In addition, a higher proportion of premenopausal patients (38%) had a family history of breast cancer, compared with the postmenopausal patients (22%). Thus, genetic factors are more important in the etiology of premenopausal breast cancer. (24 refs)

544 **Endocrine Status in Normal British, Japanese and Hawaiian-Japanese Women.** (Eng) Hayflick, J. L. (Breast Unit, Guy's Hosp., London SE1 9RT, England); Greenwood, F. C.; Glober, G.; Stemmerman, G.; Brook, R. D.; Wang, D. Y.; Kumaokas, S. *Eur J Cancer* 11: 1221-1228; 1978.

The hypothesis that there are no major differences in endocrine function among women with Japanese ancestry in Hawaii, Japanese women, and British women that would account for the differences in breast cancer incidence among these racial groups was investigated. Women were divided into three menstrual groups based on menopausal status. There were no differences in plasma and urinary estrogens among premenopausal women of the three racial groups. The postmenopausal Hawaiians had a higher plasma and urinary estrone level and a lower plasma progesterone level than British

or Japanese women. In postmenopausal Hawaiian women, plasma estradiol levels were significantly lower than those in the other two groups. The differences in androgen status were very complex: plasma androstenedione and urinary 11-deoxy-17-ketosteroid and etiocholanolone levels were lower in Hawaiian than British women and resembled those in Japanese women, but plasma dehydroepiandrosterone levels were higher in Hawaiians than in Japanese and resembled those in British women. This study reinforces the conclusion that ovarian and pituitary hormone levels do not explain the differences in incidence of breast cancer among the three groups and suggests that changes of environment bring about some alterations of endocrine function, mainly in the androgens. (39 refs)

78-6545 **Cancer of the Brain in Hawaii.** (Eng) Korsak, R. K. (Cancer Center Hawaii, Univ. Hawaii, Honolulu, HI); Rashad, M. N. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 2225-2228; 1978.

The incidence of malignant brain tumors in Hawaii was studied for two periods, 1960-1964 and 1968-1972. Age-specific incidence rates and age-adjusted rates were computed by sex and race (Caucasian, Chinese, Filipino, Hawaiian, and Japanese). There was a total of 162 brain tumors: 68 occurred during the first period, 94 during the second period. The age/race-incidence rates were 1.9/100,000 women and 2.2/100,000 men for the early period. During the later period, the incidence was 2.2/100,000 women and 2.7/100,000 men. There appeared to be significant racial differences, with Caucasians and Hawaiians having higher incidence rates than the other racial groups. Mortality due to malignant brain tumors was highest among Caucasian men and Hawaiian women. These results confirm the gradient between Caucasians and Orientals for brain tumors. (11 refs)

78-6546 **Cancer among Hawaiians and Part-Hawaiians.** (Eng) Rashad, M. N. (Dept. Genetics, Cancer Center Hawaii, Univ. Hawaii, Honolulu, HI); Mi, M. P.; Budy, A. M. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detec-

tion and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 2209-2218; 1978.

Cancer incidence among Hawaiians and part-Hawaiians was analyzed for the period 1968-1972. Of the total 1,057 cancer patients, 465 were women and 592 men. Age-specific and age-adjusted incidence rates were computed for selected sites. The age-adjusted annual incidence rate per 100,000 was 243.6 for men and 258.1 for women. The most common cancer in men was cancer of the lung, which accounted for 25% of all cases, followed by cancer of the stomach (8.6%). In women, the most frequent cancers were cancer of the breast (21.3%) and cervical cancer (17.2%). Comparison with other racial groups (Caucasian and Japanese) showed that Hawaiians and part-Hawaiians have the highest incidence rate of cancer of the lung and of the corpus uteri. This study confirms earlier reports of an excess of cancer among Hawaiians and part-Hawaiians. (30 refs)

78-6547 Contribution to the Problem of the Association of Silicosis and Lung Carcinoma. (Ita) Cardesi, E. (Servizio di anatomia e istologia patologica, Ospedale San Luigi Gonzaga di Orbassano, Turin, Italy); Provana, A. *Patologica* 70(1005/1006): 377-401; 1978.

Data on 204 patients with silicosis and/or pulmonary carcinoma diagnosed at autopsy or by postoperative histological examination at an Italian Hospital during 1975-1976 were tabulated and analyzed. Age, sex, profession, tumor histology and site, type of silicosis, and the carcinoma-silicosis association were considered. There were 135 patients with pulmonary carcinomas (116 men aged 34-81 yr and 19 women aged 50-81 yr). These tumors were subdivided into epithelial carcinoma (49 men, 3 women), microcytoma (17 men, 3 women), adenocarcinoma (18 men, 5 women), anaplastic and large cell carcinoma (26 men, 3 women), and bronchial-alveolar carcinoma (6 men, 5 women). The most frequent sites were the superior (60/135) and inferior lobes (34/135). Of the 32 silicosis patients, 29 were men (aged 40-80 yr) and 3 were women (aged 44-61 yr). Silicosis was classified as massive (10 men, 2 women), nodular (8 men, 1 woman), and peribronchial-vascular (11 men). Thirty-seven patients had both conditions (34 men aged 41-80 yr and 3 women aged 62-80 yr). The most frequent sites for silicosis-carcinoma were superior lobe (15/37), inferior lobe (12/37), and principal bronchus (5/37). Epithelial carcinomas were most common, and they were associated with all types of silicosis: massive (3/37), nodular (5/37), and peribronchial-vascular (7/37). Because of a lack of information, no statistically valid conclusions could be drawn on the association of various professions with silicosis or carcinoma. No statistically valid correlation could be made between the type of silicosis and the histological type of carcinoma. An indirect causal relationship may exist between silicosis and pulmonary carcinoma. (36 refs)

78-6548 Epidemiologic Studies of Cancer in Man and Animals Sharing the Same Environment. (Eng) Schneider, R. (Animal Neoplasm Registry, Dept. Epidemiology and Preventive Medicine, Univ. California, Sch. Veterinary Medicine, Davis, CA, 95616). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol 2(part 1), 2404 pp.; 1377-1378.

The patterns of human and animal cancer in the same environment were examined by comparing the incidence rate and sex pattern for the major sites of cancer found in humans, dogs, and cats in two California counties: Alameda and Contra Costa. Animal ages were converted to human age-equivalents, and both the human and animal crude incidence rates were age-adjusted to the same population age distribution determined by the 1950 US census. Human cancer rates were at least threefold higher than dog or cat rates for six sites: lung, bladder, digestive tract, prostate, ovary, and uterus. Possible reasons for these excess cancers are given. Cancer rates were threefold higher in the gum and testis, and feline rates were threefold higher for leukemias and lymphomas. Sex rate ratios for cancer showed excess male cases for humans and cats and excess female cases for dogs. Sex rates at specific sites indicated better agreement between humans and cats than between humans and dogs. Comparison of cancer occurrence in three species under similar conditions may help elucidate how cancer is expressed at specific sites. (10 refs)

78-6549 Association of Squamous Cell Carcinoma of the Head and Neck with Cancer of the Esophagus. (Eng) Goldstein, H. M. (Dept. Diagnostic Radiology, University of Texas System Cancer Center, M.D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030); Zelen, J. *Am J Roentgenol* 131(5): 791-794; 1978.

The association between esophageal cancer and squamous cell carcinoma of the head and neck region (oral cavity, pharynx, and larynx) was studied by reviewing hospital files for the period March 1944 to August 1976. Eighty-nine patients were found who had separate primary squamous cell tumors of the head and neck and of the esophagus, representing 10% of all patients with esophageal carcinoma evaluated at the institution. In >80% of the patients, the separate primary tumors were discovered asynchronously (2 mo-16 yr apart). The expected number of esophageal carcinomas among the 10,000 patients with head and neck cancer was 10, compared with the 89 observed. The number of second primary tumors of the stomach and colon among the head and neck cancer population was not greater than anticipated. Most patients

a longstanding history of considerable cigarette and alcohol use. These findings suggest that alcohol and tobacco etiologic factors linking these two primary cancer groups, they indicate the importance of complete radiological evaluation of the esophagus in head and neck cancer patients. (5 refs)

6550 **Fluoridation of Water Supplies and Cancer - A Possible Association?** (Eng) Oldham, P. D. RC Pneumoconiosis Unit, Llandough Hosp., Penarth, S. (morgan, Wales); Newell, D. J. *J R Stat Soc Ser C* 2: 125-135; 1977.

a from a recent study of the crude cancer mortality rates in 10 US cities with fluoridated water supplies and 10 US cities with nonfluoridated water were reexamined to determine whether the conclusion that nationwide fluoridation would lead to excess cancer deaths was justified. At the beginning of the study (1950), the cities with fluoridated water had fewer elderly white men and women, more nonwhites aged 60 yr, and a greater proportion of cancer deaths than those in nonfluoridated water. At the end of the study, the cities with fluoridated water had many more nonwhites of all ages and fewer whites aged <55 yr than those with nonfluoridated water. Taking these variables into account, the excess cancer rate increased by 1% over the study period in the cities with fluoridated water and by 4% in those with nonfluoridated water. In absolute terms, the excess cancer rate between 1950 and 1970 increased by 8.8/100,000 in those with nonfluoridated water. It is concluded that the study provided no evidence that fluoride increases cancer mortality. (7 refs)

6551 **Cancer Epidemiologic Surveillance in the Du Pont Company.** (Eng) Pell, S. (Medical Div., E. I. duPont de Nemours and Co., Wilmington, DE, 19898); Berg, M. T.; Karrh, B. W. *J Occup Med* 20(11): 725-740; 1978.

The surveillance program started at the Du Pont Company in 1956 is described, and employee morbidity and mortality statistics are presented for the period 1956-1974. With certain exceptions, age-specific cancer incidence and mortality ratios were lower than those found in the Third National Cancer Survey. For men, the incidence ratio for all forms of cancer was 79 and the mortality ratio was 82. The corresponding ratios for women were 111 and 82. Mortality differences between Du Pont and the US decreased with increasing age. The incidence of malignant skin melanoma in men was significantly higher than expected, based on NCI data (Standard Incidence Ratio, SIR = 123, $P < 0.05$). The magnitude of the excess was slightly higher in salaried men (SIR = 127) than in wage role employees (SIR = 121). A significant excess of intestinal cancer occurred in salaried men employees (SIR = 117, $p < 0.05$). Among women, cervical cancer incidence was significantly higher than expected (SIR = 233, p

< 0.05), and it was especially high among the wage roll employees (SIR = 296). Breast cancer incidence was significantly higher in salaried employees (SIR = 136, $p < 0.05$), but was lower than expected in wage roll employees (SIR = 81, $P < 0.05$). Among salaried women employees, there were 11 cases of leukemia, which was significantly greater than the expected 6.1 ($p < 0.05$). Primary sites for which the incidence rates were especially low were for men: the thyroid, larynx, prostate, and buccal cavity, and pharynx; and for women, the lung. Cancer morbidity and mortality rates for the entire company cannot be relied on to indicate an increased risk of cancer resulting from exposure to a particular carcinogenic substance in the company. (16 refs)

78-6552 **Nasopharyngeal Carcinoma Patients in Massachusetts.** (Eng) Goodman, M. L. (Dept. Otolaryngology and Pathology, Massachusetts Eye and Ear Infirmary, James Homer Wright Pathological Lab., Massachusetts General Hosp. and Harvard Medical Sch., Boston, MA); Levine, P. H.; Miller, D. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1591-1598; 1978.

Possible etiological mechanisms of genetic susceptibility and Epstein-Barr virus (EBV) infections in nasopharyngeal carcinoma (NPC) were investigated. Thirty patients treated for NPC from 1972 to 1975 and controls matched by age (within 5 yr), race, sex, and level of education were evaluated for antibodies to EBV viral capsid antigen (VCA) and early antigen (EA). In addition, patients and controls were questioned about their personal habits and dietary practices. The two groups did not differ in the proportion of individuals reporting the use of coffee, tea, alcoholic beverages or cigarettes, although the NPC patients were heavier smokers than the controls (47% vs 22%, respectively, smoked 2 packs or more per day). VCA antibody determinations varied from 1:160 to 1:2560 for NPC patients and 1:40 to 1:1280 for controls, with respective median values of 736 and 370. EA antibody levels were also higher in NPC patients, 13/26 patients having titers of 160 and above, compared with 2/27 controls. Elevated VCA and EA antibodies, low socioeconomic status and heavy smoking habits were the most frequent consistent findings in the NPC group. (4 refs)

78-6553 **Incidence Rates and Risk Factors of Benign Breast Neoplasms.** (Eng) Cole, P. (Dept. Epidemiology, Harvard Sch. Public Health, 677 Huntington Ave., Boston, MA, 02115); Elwood, J. M.; Kaplan, S. D. *Am J Epidemiol* 108(2): 112-120; 1978.

A case-control study of benign breast disease was conducted in the Greater Boston area during 1968-1969. The cases were 938 women initially diagnosed as having fibrocystic disease (FD), fibroadenoma (FA), or a mixed lesion (ML) during the 18-mo study period. Controls were a random sample of the entire reference population. Mailed questionnaires were completed by 678/938 benign breast disease women and 1,807/2,062 controls contacted. Information on factors known to be related to breast cancer was obtained, to allow the similarities of the two conditions to be assessed. The age-standardized incidence rate for FD and FA was 89.4 and 32.8 per 100,000 woman-yr, respectively. The incidence of FD rose to age 45 and then declined sharply, that of FA peaked during the 20's, and that of ML had a mode at age 30-34. Among young women, the highest rates occurred in married nulliparae, but this was not so at higher ages. The incidence of FD and FA did not follow a pattern consistent with parity or age at first birth. The risk of FA increased with late age at menarche and that of FD increased with later natural menopause and with artificial menopause at any age. The risk of FD, but not of FA, also increased in women with arthritis and women in higher socioeconomic groups. The relative incidence of all three benign breast diseases decreased steadily with increasing obesity. The epidemiologic pattern of FD and FA did not correspond to that of breast cancer, which is directly related to obesity but not to age at menarche or to artificial menopause. Previous studies have indicated that the risk of breast cancer in benign disease may be limited to conditions such as severe ductular atypia or carcinoma in situ. (25 refs)

78-6554 Radiation, Smoking and Height Relationships to Lung Cancer in Uranium Miners. (Eng) Archer, V. E. (Natl. Inst. Occupational Safety and Health, Center Disease Control, US Dept. Health, Education and Welfare, 390 Wakara Way, Salt Lake City, UT, 84108). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 1689-1712; 1978.

A prospective mortality study using a life table method was done on 3,366 white underground uranium miners and 1,231 surface workers. Cumulative radon daughter exposure values were calculated for each miner from the date of his first mining to each sequential month of observation through September 1969. Miners were classified into tobacco groups on the basis of cigarette use only. Observed deaths exceeded those expected from respiratory cancer (146 vs 30), pneumoconiosis and related diseases, and accidents related to work. The overall rate of death from respiratory cancer among the miners was 4.9 times greater than that expected from general population data and 6.0 times greater than that found among the control group of surface workers. Exposure-response rela-

tionships with radiation varied with the height of the workers, cigarette smoking, and latent period between start of mining and disease. Of the four factors involved in malignant and nonmalignant respiratory diseases (high free silica, cigarette smoking, and alpha radiation), radiation was the most important. The clinical observation that short uranium miners have more lung disease than larger miners was substantiated by the data gathered in this study. Miners are engaged in physical labor, and tall men have larger lungs so it is postulated that short miners receive a higher dose of noxious agents per unit of lung tissue when performing heavy work. It is concluded that standards for airborne noxious agents should consider the amount of physical labor involved and the size of individual workers. (20 refs)

78-6555 A Comparison Model Approach to the Estimation of Tumor Incidence and Growth: Investigation of a Model of Cancer Latency. (Eng) Tolley, H. (Dept. Statistics, Texas A & M Univ., College Station, TX 77843); Burdick, D.; Manton, K. G.; Stallard, E. *Biometrika* 34(3): 377-389; 1978.

The nature of cancer, with its lengthy latent period, makes collection of data on the entire process of carcinogenesis difficult, as the early rate and pattern of tumor growth are unserved. Stochastic compartment modeling is proposed to solve the problems of estimating the transition probabilities of a partially observed stochastic process. The goal of the model is to synthesize the results of various studies into a coherent model of cancer latency and general population incidence of cancer. The rate coefficients for a time-dependent multiple compartment system were estimated for cancer-susceptible and nonsusceptible portions of a population, with individual rate coefficients being identified as explicit functions of age and tumor growth times. Under the model, tumor latency is relatively lengthy and if the population being studied is elderly, many tumors may not become clinically manifest due to mortality from other diseases. Susceptibility affects the model by fixing the proportion of persons who may get cancers. The model, with parameters representing tumor incidence, time to tumor death given onset, genetic susceptibility to tumor growth, and the effects of competing forces of mortality, was fitted to data on 1969 deaths due to stomach cancer for US men aged ≥ 25 yr. Two forms, one with waiting time distribution for occupants of the latent state and one with a single latency time, achieved excellent fits to the data. (33 refs)

78-6556 Associations of Cancer Mortality with Halomethanes in Drinking Water. (Eng) Cantor, K. (Health Effects Res. Lab., U.S. Environmental Protection Agency, Cincinnati, OH, 45268); Hoover, R.; Mason, T. McCabe, L. J. *J Natl Cancer Inst* 61(4): 979-985; 1978.

Age-standardized cancer mortality rates by site and sex f

tes in 76 US counties were compared with levels of chloroform, bromine-containing trihalomethane(s) (BTHM), and trihalomethane(s) (THM) in the drinking water. The 76 counties are > 50% urban, and over half the population is served by a sampled water supply. Using several demographic, socioeconomic, and industrial variables, a predicted mortality rate was computed and compared with the actual rate. The resulting residual mortality rate for each county was compared with the level of one of the three THM indicators using the bivariate correlation coefficient. Counties were grouped according to the overall percentage of the county served by the sampled water supply (low, intermediate, or high) and by geographic location. Bladder cancer residual mortality in both sexes showed a strong correlation with THM. This correlation persisted in spite of controls for sex, age, class, ethnic group, urban vs rural residence, presence of specific high-risk industries, and lung cancer rates (possible surrogate for levels of cigarette smoking). Brain cancer was not correlated in both sexes, but the associations were not strong, and there was regional variation. Other sites that gave indications of an association were: CHCl₃ levels and male kidney cancer, BTHM and female lung cancer, and THM levels and non-Hodgkin's lymphoma in men. Stomach cancer in women showed a negative correlation. (23 refs)

78-6557 **A Critique of the Statistical Evidence Associating Estrogens with Endometrial Cancer.** (Eng) Weinstein, A. R. (Dept. Medicine, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Horwitz, R. I. *Cancer Res* 38(11, 12): 4001-4005; 1978.

Several types of bias that may have influenced the estrogen-endometrial cancer (E-EMC) association are described. In postmenopausal women with EMC, detection bias is produced because of the dilation and curettage or other diagnostic tests ordered when bleeding occurs as a side effect of E therapy. These tests allow the detection of EMC's that might otherwise be silent and undetected in women who do not take E. The problems of detection bias have been ignored in most case-control studies and they are difficult to deal with, as the bias occurs before cases and controls enter the study. To reduce this bias, the conventional method of epidemiological selection must be altered. Instead of two individual groups being chosen, both cases and controls can be selected from a single sampling frame consisting of people referred for performance of the particular diagnostic test used to identify the target disease. The bias can be reduced further by stratifying patients according to the cogent clinical reason that led to their referral to the hospital for the diagnostic test. Other sources of bias for the E-EMC association include the inadvertent prescription of E's for women with unrecognized EMC, the absence of double-blind interviewing techniques, and arbitrary definitions of exposure to E's. The current controversy about E's and EMC is a result of the inadequacy of conventional methods used for epidemiological research in chronic disease. (18 refs)

78-6558 **Geographic Patterns of Prostate Cancer in the United States.** (Eng) Blair, A. (Environmental Epidemiology Branch, Div. Cancer Cause and Prevention, NCI, NIH, Bethesda, MD, 20014); Fraumeni, J. F. *J Natl Cancer Inst* 61(6): 1379-1384; 1978.

Age-adjusted rates of mortality from prostate cancer during 1950-1969 were correlated by race with demographic, industrial, and agricultural data from 3,056 US counties. Prostate cancer was rare in young whites and nonwhites, increased progressively after 35 yr of age, and reached a plateau after 75 yr of age. Among whites, mortality rates in the midwest and northcentral regions were significantly higher than the total US rate, but the relative difference between the lowest and highest regional rates was only 8%, which is considerably less variation than that seen among whites with other tumors. Mortality among nonwhites was 50% higher than that among whites in all parts of the country where blacks comprise most of the nonwhite population. The rising rate associated with population density among nonwhites, but not whites, suggests that environmental exposures related to urban living may account for the predisposition of American blacks to prostate cancer. Mortality was elevated in counties with a high percentage of residents of Scandinavian descent, consistent with the high incidence reported for Sweden, Norway, and Denmark. Mortality was also elevated in counties with metal-using and textile industries and in regions with high consumption of high-fat foods. (46 refs)

78-6559 **Colon Cancer in a Low-Risk Population.** (Eng) Lyon, J. L. (Dept. Family and Community Medicine, Univ. Utah Coll. Medicine, Salt Lake City, UT, 84132); Sorenson, A. W. *Am J Clin Nutr* 31(10): S227-S230; 1978.

Colon cancer (CC) incidence from 1966 to 1970 was studied for the state of Utah, which had a CC mortality 34% below the US average during 1950-1969. The 10,641 cancer cases over this 5-yr period were compared to the age incidences of the Third National Cancer Survey (TNCS), broken down as to religious group (6,412 were Mormons), and computed as standard incidence ratios (SIR). The overall cancer SIR for the Mormon population was 75.6; for the non-Mormons, 93.9. For CC specifically, the corresponding SIR was 62.9 and 81.6, respectively. Mormons had a significantly lower risk of cancer of esophagus and lung than non-Mormons, due presumably to their religious ban on tobacco and alcohol. Furthermore, Mormon women had cancer incidence rates significantly lower than TNCS values at the colon-correlated sites of corpus uteri, breast, and ovary. Because per capita beef consumption in Utah is greater than the national average, and the anatomic distribution of colon cancer was not different between religious groups, Utah Mormons do not seem to adhere to a vegetarian diet. This conclusion, coupled with the low incidence of colon cancer, does not support the current hypothesis relating meats, fats, and dietary fiber to colonic cancer. (18 refs)

- 78-6560 Mortality in Unionized Truck Drivers.** (Eng) Luepker, R. V. (Lab. Physiological Hygiene, Stadium Gate 27, Univ. Minnesota, Minneapolis, MN, 55455); Smith, M. L. *J Occup Med* 20(10): 677-682; 1978.

Mortality rates among 184,435 male members of the Central States Teamsters Union during May-July 1976 were determined by surveying death certificates issued during that period and then comparing them with the rates for the general US population (GP). In this period, 249 deaths occurred, with the two leading causes being cardiovascular disease (104) and cancer (72). Except for respiratory tract cancer and motor vehicle accident deaths, mortality rates were lower than those in the GP and comparable to those in other employed populations. The mortality rate for all cancers paralleled and was not significantly different from that found in the GP. Respiratory tract cancers, mainly cancer of the lung, were the leading cause of death in the cancer category, accounting for 48% of the cases. Respiratory tract cancer mortality among the teamsters was in slight excess at ages 40-49 and 60-69 and significantly higher at ages 50-59 than that in the GP. It was not possible to separate the effect of cigarette smoking from environmental exposure to explain the excess respiratory tract cancer mortality. (12 refs)

- 78-6561 Occupational Cancer in Chromium Factory Workers.** (Jpn) Sano, T. (Dept. Pathology Occupational Diseases, Inst. Science Labor, Kawasaki-shi, Kanagawa Prefecture 213, Japan); Ebihara, I. *Jpn J Chest Dis* 37(2): 91-101; 1978.

Inflammation and cancer of the skin and mucosa of respiratory tract organs and, also, organs of the digestive tract have been found in chromium factory workers. These lesions are caused by the interaction of Cr and nickel, carcinogenic and inflammatory agents that infiltrate into the body during Cr production, with manganese and vanadium, inflammatory agents. Trivalent Cr plays a leading role in chronic inflammation and carcinogenesis. As of August 1975, there were 17 deaths due to lung cancer, 21 due to cancer of the respiratory organs, and 11 due to cancer of other organs (3 stomach cancers, 4 liver cancers, 1 neck sarcoma, 1 acute lymphatic leukemia, 1 reticulum cell sarcoma, and 1 renal cancer) among former Cr factory workers. Continued inflammatory stimulation induces repeated degeneration and regeneration of cells, leading to instability of the intranuclear gene and, hence, formation of an acquired factor for carcinogenesis. (27 refs)

- 78-6562 Cancer Epidemiology. Series No. 7: Solid Lymphomas in New South Wales.** (Eng) Ford, J. (Central Cancer Registry, Health Commission of NSW, GPO Box 4235, Sydney, New South Wales 2001, Australia). *Cancer Forum* 14: 111-114; 1978.

The incidence of solid lymphomas in New South Wales 1972 was investigated using data from the New South Wales Statutory Cancer Notification Form. Solid lymphomas include all cancers classified as lymphosarcomas, reticulosarcomas, Hodgkin's disease, giant follicular lymphoma, mycosis fungoides, and other malignant lymphomas, including those originating in organs other than lymph nodes. In 1972, the incidence of new cases was 246 for men (5% of cancers) and 212 for women (4% of new cancers). The incidence of solid lymphomas is greatest in the older age group (70 yr and over). There were 288 deaths from this cancer in 1972: 163 in men and 125 in women. There is no evidence that the lymphomas are transmitted by close personal contact. (no refs)

- 78-6563 High Incidence of Metalworkers among Patients with Testicular Cancer.** (Eng) Rhomberg, W. (Dept. Radiotherapy and Special Oncology, Sch. Medicine, Hannover, W. Germany); Schmoll, H. J. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer, by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404-1737-1743; 1978.

Forty-five patients who had undergone radiation therapy for a malignant testicular tumor in 1969-1974 were interviewed to obtain occupational and medical histories. The original diagnoses were as follows: 27 seminomas, 8 teratocarcinomas, 5 embryonal cell carcinomas, and 5 mixed forms. Nine of the patients were skilled metalworkers, and an additional seven patients had formerly been employed in this industry. The group of metalworkers included locksmiths, moldmakers, turners, car mechanics, electromechanics, and tool makers. Occupational exposure to metal compounds or metal dust ranged from 4 to 24 yr. Of the 19 nonmetalworkers, 11 had a history of exposure to metals (for 2-26 yr) that related directly or indirectly to their occupation, and other patients were exposed to metals as a result of a hobby. Only 9/45 patients showed no overt exposure to metals lasting for several years. (11 refs)

- 78-6564 Soft-Tissue Effects Following ²²⁴Ra Injection into Humans.** (Eng) Spiess, H. (Kinderpoliklinik, Universitat Munchen, Munich, W. Germany); Cech, A.; Mays, C. W. *Health Phys* 35(1): 61-81; 1978.

The soft-tissue effects of iv injections of radium-224 for treatment of tuberculosis, ankylosing spondylitis, and several other diseases were investigated in 204 patients treated as juveniles (1-20 yr old) and 612 treated as adults. Dosage and injection span were known in all patients. The average follow-up time from the first injection was 17 yr for the adults and

for the juveniles. Eighteen men injected as adults and two juveniles developed neoplasms, compared with 25 expected. Seventeen women injected as adults and three as juveniles developed cancer, exceeding the eight expected cases. However, when the male and female cases were combined, the 38 observed agreed closely with the 33 expected, suggesting that most of the soft-tissue neoplasms appearing so far are naturally occurring rather than related to ^{224}Ra therapy. Certain types of malignancy did occur at a rate above the expected value: leukemia (2 observed vs 0.8 expected), breast cancer (5 vs 1.2-1.8 expected), and renal cell carcinoma (3 vs 0.6-1.1 expected), which suggests that they might have been radiation-induced. More may appear later because of the latent period characteristic of radiation-induced cancer in humans. (41 refs)

78-6565 Soft Tissue Sarcomas and Intramuscular Injections: An Epidemiological Survey. (Eng) McIlroy, M. B. (Univ. Dept. Therapeutics, City Hosp., Nottingham NG5 1BB, England); Langman, M. J. *Br Med J* 3(41): 864-865; 1978.

Records of patients presenting with soft tissue sarcomas during 1974-1975 in the Trent, England, area were analyzed to determine whether the tumor could have been the result of previous intramuscular injections of iron preparations. Of 46 traceable patients with tumors on the leg, 12 had tumors at sites where injections might have been given, but only 2 cases arose specifically in the buttock. Records of all 46 patients were investigated, and no history of allergy, iron deficiency, or previous treatment by injections of any sort was noted. Likewise, of 19 traceable patients with sarcomas on the arm, 5 had tumors in an area where injections might have been given, but all 19 records proved negative for the types of information sought. These findings, therefore, do not support the suggestion of a causal relationship between sarcoma formation and intramuscular injections of iron or other preparations. (5 refs)

78-6566 Frequent Elevation of Tissue Polypeptide Antigen in the Sera of Workers Exposed to Bladder Carcinogens. (Eng) Kumar, S. (Christie Hosp. and Holt Radium Inst., Withington, Manchester M20 9BX, England); Mason, P.; Brenchley, P.; Taylor, G.; Bjorklund, B.; Eklund, M. *Int J Cancer* 22(5): 542-545; 1978.

Elevated levels of tissue polypeptide antigen (TPA), a substance purified from human tumors and placenta, have been found in sera from cancer patients. The diagnostic, prognostic, or epidemiological significance of sequential determinations of serum TPA levels was evaluated by comparing the results of these determinations in 108 male chemical workers exposed for at least 6 mo to 1-naphthylamine, 2-naphthylamine, benzidine, or a combination of these chemicals; 26 bladder cancer patients; and 63 healthy men. TPA was estimated by a hemagglutination-inhibition technique. The proportion

of individuals with a raised TPA level among the workers and patients was significantly higher (40/108 and 11/26) than that among the normal men (6/63). However, there was no significant difference in the proportion of positives between the workers and patients. It is suggested that a raised serum TPA level may be a very early indicator of hyperplastic bladder epithelium. (18 refs)

78-6567 Management of Urinary Bladder Cancer. (Eng) Fichardt, T. (Dept. Radiotherapy, H. F. Verwoerd Hosp., Pretoria, S. Africa); Sandison, A. G. *S Afr Med J* 54(18): 731-740; 1978.

From 1960 to 1976, 231 patients (198 men, 33 women) with primary cancer of the bladder were referred to a South African Hospital, and the etiology and clinicopathology of this disease are surveyed based on analyses of these patients and the literature. There were 115 transitional cell carcinomas, 87 anaplastic carcinomas, 15 squamous cell carcinomas, 12 papillary carcinomas, and 2 adenocarcinomas among the study group. Most (90%) of the patients presented with hematuria alone; the others presented with hematuria plus frequency and dysuria, incontinence, and bladder calculi. The duration of symptoms ranged from 2 wk to 2 yr, but most lasted 3-6 mo before diagnosis. The lesions were mostly single, situated mainly on the lateral and posterior walls and on the trigonum. Predisposing factors are numerous and varied, but cigarette smoking poses the greatest hazard for the general population. Cigarette smoking blocks the normal metabolism of tryptophan, leading to an accumulation of carcinogenic metabolites of tryptophan in the urine. The basic abnormality is an inability to convert 3-hydroxyanthranilic acid to nicotinamide. Other possible etiologic agents include the aromatic amines used in the dyestuff, rubber, and plastic industries; pesticides, especially those containing naphthylamines; dyes used in the manufacture of foods, cosmetics and drugs; bilharziasis; and coffee-drinking. Bladder calculi and bladder papillomas may also predispose to bladder cancer. (53 refs)

78-6568 Cancer in Cameroon: A Relative Frequency Study. (Eng) Jensen, O. M. (Unit Epidemiology and Biostatistics, International Agency Res. Cancer, 150 Cours Albert-Thomas, 69008 Lyon, France); Tuyns, A. J.; Ravis, P. *Rev Epidemiol Sante Publique* 26(2): 147-159; 1978.

Cancer was diagnosed and confirmed histologically in 1,390 males and 1,418 females in Cameroon, Africa, during 1969-1973. An attempt was made to correlate the cancer pattern with ethnic differences in the state. In both sexes, the pattern was dominated by a few tumor sites: men--skin 30%, malignant lymphomas 13%, and primary liver cancer 11%; women--skin 30%, uterine cervix 16%, and breast 10%. Ethnic differences were more apparent among men than women,

and they were correlated with neoplasms of the pharynx and buccal cavity, lung, connective tissue, and genitourinary tract. A close examination of tumor time trends showed that liver and respiratory tract tumors increased more rapidly than the total number of cancers. On the other hand, the same absolute number (a decreasing proportion) of skin cancers was recorded during each year of the study. These results suggest that the time trends reflect rapid changes in society and in medical facilities rather than actual changes in the frequencies of these tumors. For this reason, the results should be interpreted cautiously. (28 refs)

- 78-6569 Sperm Basic Proteins and Cervical Carcinogenesis (2 Letters to Editor).** (Eng) Reid, B. L. (Dept. Obstetrics and Gynaecology, Univ. Sydney, Sydney, N.S.W., 2006 Australia); French, P. W.; Hagan, B. E.; Coppleson, M. *Lancet* 2(8093): 788-789; 1978.

Two hundred and three men, only 3 of whom were students, were examined in a previous study to determine the correlation between two sperm basic proteins, histone and protamine, and social class. Recasting of the data in nonparametric terms using the analysis of variance by ranks of Kruskal-Wallis showed a correlation that was even more significant than that found originally. Differences in the incidence of cervical cancer by social class are marked and are among the greatest of all differences known. It is possible that the importance of the environment as a constant correlate of social class difference may operate through a subtle direct effect on cellular nucleic acids. A poor environment may impoverish the genome. However, it is important to determine the effects of increased sexual activity, multiple partners, genital herpes, and intercourse only with men who wear condoms or have been vasectomized on cervical cancer incidence before coming to any definite conclusions concerning etiology or prophylaxis. (8 refs)

- 78-6570 Cancer in Eastern Caribbean Islands.** (Eng) Rao, E. V. (Radiotherapy Dept., Public General Hosp., Kingston, Jamaica, W. Indies). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(Part 1), 2404 pp.; 2229-2240; 1978.

The incidence of cancer in the Eastern Caribbean Islands, based on data from the Eastern Caribbean Cancer and Clinical and Pathological Registries, was determined and compared with that in Africa, as 89% of the island residents are Negro. Since most of the islands did not keep cancer statistics, the data pertain mainly to Barbados, which contains more than half the total island populations. In 1971, there were 359 cases of cancer in Barbados, 221 in women and 138

in men. The most common types were in women, 76 of cervical carcinoma and 54 cases of breast cancer. There were no cases of male breast cancer. In men, cancer of stomach (18 cases), esophagus (12), and prostate (20) were most prevalent. Skin cancer showed a high rate in both men and women, 28 cases in men and 23 in women. The tumor incidence in other eastern Caribbean Islands (St. Vincent, St. Lucia, Dominica, etc.) was similar to that seen in Barbados except for a high incidence of bone tumors in St. Vincent. Hepatomas, lymphosarcomas, or leukemias, which are common cancers in Africa, were observed among the population of the Eastern Caribbean Islands. This may be due to changes in geography, environment, and/or social customs. (11 refs)

- 78-6571 Relation of Dysplasia and Carcinoma of the Uterine Cervix to Age at Onset of Sexual Activity and Number of Coital Partners.** (Eng) Berget, A. (Jul 4, DK-2820 Gentofte, Denmark). *Dan Med Bull* 25: 172-176; 1978.

Several risk factors in the development of dysplasia (D) or cervical carcinoma (CC) were investigated using subjects who took part in a CC screening test in a Danish county. The study comprised 67 women with a positive test (40 with D and 27 with CC) and 488 controls with a negative test, all aged 30-55. The risk of developing D or CC increased with increasing age at onset of sexual activity, evaluated from age at first coitus and at first pregnancy. The risk also increased with number of sexual partners, and this risk applied after corrections for social status and age at onset of sexual activity were made. The lower the social status the earlier the onset of sexual activity and, in contrast to controls, women with CC or D had an increasing number of sexual partners with decreasing social status. Thus, the risk of the two conditions increased with decreasing social status. Compared with the middle stratum, the risk was almost five times higher in the low and four times lower in the high stratum. Age at coitus and number of sexual partners were considered of practical use for identifying high-risk groups. In contrast to socioeconomic classification of women by their early education, used here, seems applicable to population screening. The correlations between sexual behavior and D or CC support the theory that the lesions are caused by an infectious agent. (29 refs)

- 78-6572 Diet, Transit Time, Stool Weight, and Cancer in Two Scandinavian Populations.** (Eng) MacLennan, R. (International Agency Res. Cancer, Cours Albert Thomas, 69372 Lyon, Cedex 2, France); Jensen, O. M.; Mosbech, J.; Vuori, H. *Am J Clin Nutr* 31: S239-S242; 1978.

Diet, stool transit time, and stool weight were compared in males, 55-64 yr of age, from urban Copenhagen, Denmark (CD), and rural Kuopio, Finland (KF), to investigate

fold differences in age-adjusted colon cancer incidence and in the two Scandinavian populations. Interviews and a food and drink diary kept for four consecutive days showed that the high incidence CD subjects consumed significantly more white wheat breads, total meats, pork, and beer, and less potatoes and milk. Although constipation and delay in stool passing were more common in CD, frequency of defecation and transit time were similar in both populations, with transit time showing a bimodal distribution. Stool weight was significantly higher in low incidence KF in autumn. Simple correlation coefficients of transit time and stool weight with bowel habits and diet components were calculated, and most correlations were low. In the 5/84 significant relationships that did exist between various foods and transit time or stool weight, all were negative, and the maximum absolute value of the coefficient was 0.28. Although the fiber hypothesis of colon cancer etiology was supported by computed fiber values (30.9 g/day in KF versus 17.2 in CD), the corresponding shorter mean transit time expected in KF was not noted. (0 refs)

78-6573 **Age at Menarche and Menopause of Uterine Cancer Patients.** (Eng) de Graaff, J. (Dept. Obstetrics and Gynecology, Vrije Universiteit, Amsterdam, Netherlands); Stolte, L. A. *Eur J Obstet Gynecol Reprod Biol* 44: 187-193; 1978.

The ages at menarche and at menopause of 868 cervical and endometrial cancer patients diagnosed during 1950-1955 and 1960-1965 were investigated. The mean age at menarche for all the cancer patients occurred in accordance with the literature, at an earlier age during 1960-1965 (13.88 yr, cervical cancer group; 14.03 yr, endometrial cancer group) than during 1950-1955 (14.08 and 14.24 yr, respectively). Analysis of the ages at menarche in relation to year of birth showed that there is no correlation between this factor and cervical endometrial cancer. However, menopause occurred later in the endometrial cancer group (49.52 yr for 1950-1955, 49.86 yr for 1960-1965) than in the cervical cancer group (47.93 yr for 1950-1955, 48.27 yr for 1960-1965). Menopause, therefore, may be a constitutional factor in the development of endometrial and/or cervical cancer. (19 refs)

78-6574 **A Note on the Use of Nitrate Fertilizers in a High-Risk Geographical Area for Stomach Cancer.** (Eng) Zaldivar, R. (International Res. Group Cancer Epidemiology and Human Ecology, 5055 N.W. 7th St., Suite 106, Miami, FL, 33126). *Z Krebsforsch* 92(2): 215-216; 1978.

In the 11 Chilean provinces that are at high risk for stomach cancer (age-adjusted mortality rates/100,000 men, 13.3-84.1), the amount of nitrate fertilizers (NaNO_3 , KNO_3) used, expressed in tons of N, was 238,950 tons. In the four low-risk provinces (mortality rates 39.1-46.2/100,000 men),

only 2,550 tons were used. The use of these fertilizers has been related to stomach cancer mortality. (6 refs)

78-6575 **Family Study of Gastric Carcinoma; With Special Reference to Histological Types.** (Eng) Lehtola, J. (Dept. Internal Medicine, Univ. Central Hosp., Oulu, Finland). *Scand J Gastroenterol Suppl* 13(50): 1-54; 1978.

The occurrence of gastric carcinoma (GC) was determined in 2,243 first-degree relatives of 341 patients (186 men and 155 women) with GC diagnosed in Uusimaa Province, Finland, during 1962-1963. Biopsy specimens of the probands were classified histologically as intestinal (139 cases), diffuse (67 cases), and undifferentiated (68 cases). In 67 cases, the type of GC could not be determined. The male/female ratio in the proband group was nearly identical to that for GC patients in the entire country (1.20 vs 1.28), but the mean age of the group was slightly lower than of other Finnish GC groups (62.6 vs 65.9 yr). The social group distribution of the patients was only slightly different from that of the entire Finnish population. The prevalence of GC among the 2,243 relatives was compared with that among 2,031 relatives of proband controls matched for sex and place and date of birth. Statistical analysis of the results revealed a relative GC risk of 1.50 in relatives of the probands vs controls ($p < 0.05$). When analyzed by cancer type, the relative risk was 1.41 for intestinal GC but 7.0 for diffuse GC ($p < 0.005$). No increased familial predisposition was noted in the probands with undifferentiated GC. When the relative with GC was the mother, the relative risks were 3.67 for the intestinal type cancer and 7.0 for the diffuse type. When several female relatives had GC, the relative risk increased to 8.0. Male cases showed little excess risk over control values. Further studies are warranted of the apparent familial clustering of diffuse GC, particularly among women. (177 refs)

78-6576 **The Incidence of Carcinoma in the Gastric Remnant after Resection for Benign Ulcer Disease.** (Eng) Ewerth, S. (Dept. Surgery, Karolinska Inst., Serafimer Hosp., Stockholm, Sweden); Bergstrand, O.; Hellers, G.; Ost, A. *Acta Chir Scand Suppl* (482): 2-5; 1978.

The incidence of cancer in the gastric remnant in 569 Swedish patients who had undergone gastric resection for benign ulcer disease during 1950-1953 was assessed. The operative technique was very consistent. There were 15 postoperative deaths. Tracing revealed that 223 patients had died, but in only 130 of these patients follow-up was adequate. Two cases with carcinoma in the gastric remnant, one found at autopsy and one radiologically verified, were found. Another patient with carcinoma of the distal esophagus and cardia was not included. Of the 253 patients who were alive when traced, 111 underwent endoscopy and biopsy. In one patient there was a severe dysplasia, but no invasive carcinomas were

found. The incidence of carcinoma in the gastric remnant found in this study was 0.8%, a value lower than that found 10-20 yr ago. The reason for this difference is not known, but it may be related to varying lengths of follow-up time or the marked overall decrease in the incidence of gastric cancer in Sweden. (16 refs)

78-6577 The Incidence of Carcinoma of the Gallbladder and Bile Ducts in Sweden 1958 to 1972. (Eng)

Broden, G. (Dept. Surgery, Karolinska Inst., Serafimer Hosp., Stockholm, Sweden); Ahlberg, J.; Bengtsson, L.; Hellers, G. *Acta Chir Scand Suppl* (482): 24-25; 1978.

The incidence of gallbladder and bile duct carcinomas in Sweden during 1958-1972 was investigated. The 5,913 reported cases were divided into three groups, each covering a 5-yr period. For each period, a mean annual incidence was calculated and related to sex and age. The absolute incidence of gallbladder and bile duct carcinomas increased during the study period. The relative incidence, however, showed a significant increase only among older patients, and especially older women. The risk of developing carcinoma of the gallbladder, which is impossible to cure, may be considered an additional indication for cholecystectomy in gallstone disease. (7 refs)

78-6578 The Changing Incidence of Malignant Melanoma of the Skin in Sweden, 1959-1968. (Eng)

Maliec, E. (Dept. Plastic Surgery, Karolinska sjukhuset, Univ. Stockholm, Stockholm, Sweden); Eklund, G. *Scand J Plast Reconstr Surg* 12(1): 19-27; 1978.

The 3,289 cases of malignant melanoma of the skin recorded in the Swedish Cancer Registry between 1959 and 1968 were analyzed with regard to sex, age, anatomical site, month of registration, and mortality. During this period, the annual

incidence rate (per 100,000) rose from 2.8 to 5.2 for men from 3.3 to 6.0 for women. The percentage annual increase for all sites was 7.0% for both men and women. The incidence rate was higher for women than for men, with a geometric annual mean of 4.4 and 4.0/100,000, respectively. The trunk was the commonest site in men, with a geometric annual mean incidence of 1.66/100,000. For women, the leg was the commonest site, with a corresponding incidence rate of 1.64. The highest increase occurred in women aged 30-39 and in men between the aged 40-64 yr. Mortality rate for malignant melanoma remained fairly constant, showing an annual change of -2% for men and +1% for women. For women, the incidence of melanoma on the legs was higher during the summer months than during the winter months. This could be a direct consequence of short-term exposure to UV radiation. 5579 **Units of Transcription for Cytoplasmic RNA in Mouse Myeloma Cells.** (Eng) Giorno, R. (Dept. Physics and Genetics, Univ. Colorado Medical Center, Denver, CO, 80262); Sauerbier, W. *Proc Natl Acad Sci USA* 75(9): 4374-4378; 1978.

Light mapping was used to estimate the sizes of transcription units for messenger RNA's (mRNA's) in mouse MPC myeloma cells. Cells were irradiated with varying doses of UV light, incubated with ³H-uridine (20-40 μCi/ml) for 1 hr in the presence of actinomycin D (0.08 μg/ml), and extracted. After the mRNA was purified from the cells, approximately 10 predominant mRNA species were resolved above a background of polydisperse mRNA by a 7 M urea/3.5% polyacrylamide slab gel system. UV-inactivation rates for the production of these major mRNA's were determined and converted to transcriptional distances in DNA base pairs. Target size analysis of the predominant mRNA's showed that they originated within transcription units that were at least 2 and possibly up to 14 times the size of the mature mRNA species. This may be a minimum estimate, since the target size for inhibiting mRNA production may have included promoter-distal sequences if they were not necessary for processing. Precursors longer than the observed target sizes may be found by complementary DNA-RNA hybridization. (34 refs)

5580 **Non-polyadenylated Messenger Ribonucleic Acids with Affinity for Polyadenyl-Sephadex** in Friend Murine Leukemia Cells. (Eng) Katinakis, P. (Dept. Biochemistry, Univ. Glasgow, Glasgow G12 8QQ, Scotland); Burdon, R. H. *Biochem Soc Trans* 6(4): 757-758; 1978.

A polyribosomal RNA fraction from Friend murine leukemia cells that has a high affinity for polyadenylic acid [poly(A)]-Sephadex was characterized. This poly(A)-binding RNA, which was isolated from polyribosomes on poly(A)-Sephadex, did not appear to be of ribosomal origin, its synthesis was unaffected by an agent that blocks ribosomal RNA synthesis. The RNA was released from polyribosomes by EDTA in a manner expected of messenger RNA (mRNA) and, after deproteinization, it sedimented in formaldehyde gradients at around 20S. Poly(A)-binding RNA appeared to lack poly(A) sequences longer than seven nucleotides, as judged by its inability to bind to polyuridylic acid [poly(U)]-Sephadex or by ³H-poly(U) hybridization. Binding of intact RNA to poly(A)-Sephadex seemed to be due to a poly(U)-rich region that also contained other nucleotides, notably guanylate residues. When introduced into a cell-free translation system, poly(A)-binding RNA stimulated the incorporation of several labeled amino acids into protein, in a manner linearly related to the amount of added RNA. In experiments in which DNA complementary to Friend cell polyadenylated mRNA was prepared using reverse transcrip-

tase and then used against poly(A)-binding RNA, little sequence homology was found. Thus, poly(A)-binding RNA is a discrete class of nonadenylated mRNA, and it has no direct relationship to polyadenylated mRNA. (16 refs)

78-6582 **DNA Modifying Enzymes of *Agrobacterium tumefaciens*: Effect of DNA Topoisomerase, Restriction Endonuclease, and Unique DNA Endonuclease on Plasmid and Plant DNA.** (Eng) LeBon, J. M. (Dept. Biochemistry, Georgetown Univ. Medical Center, Washington, DC, 20007); Kado, C. I.; Rosenthal, L. J.; Chirikjian, J. G. *Proc Natl Acad Sci USA* 75(9): 4097-4101; 1978.

Three nucleic acid enzymes of *Agrobacterium tumefaciens*, which causes crown gall disease in dicotyledonous plants, were purified and characterized. These enzymes may play a role in the infection process by catalytically activating tumorigenic genes present in the bacterium or, alternatively, by modifying plant host DNA. The first enzyme, *Atu* DNA topoisomerase, relaxed only negatively twisted DNA. The second, *Atu* I, was a type II restriction endonuclease that generated DNA digestion patterns similar to those generated by *Eco*RII with several DNA substrates. The third activity, endonuclease A, preferentially catalyzed the conversion of superhelical DNA's to their corresponding linear forms. Polyacrylamide gel electrophoresis indicated that *Atu* DNA topoisomerase unwound plasmid pCK135 DNA (obtained from the virulent strain 1D135 of *A. tumefaciens*) and had an effect on plant DNA. *Atu* I altered both plant and plasmid DNA's, but endonuclease A only altered plasmid DNA. The mobility of plasmid and plant DNA's was also altered after treatment with combinations of these enzymes, suggesting a possible role for these enzymes in vivo. (28 refs)

78-6583 **Highly Conserved DNA of Ti Plasmids Overlaps T-DNA Maintained in Plant Tumours.** (Eng) Chilton, M. D. (Dept. Microbiology and Immunology, Univ. Washington, Seattle, WA, 98195); Drummond, M. H.; Merlo, D. J.; Sciaky, D. *Nature* 275(5676): 147-149; 1978.

An attempt was made to show that part of the tumor-inducing (Ti) plasmid maintained in tumor cells (T-DNA) is highly conserved among diverse Ti plasmids. It had been suggested that since common tumor-inducing functions are a feature of every Ti plasmid, a region of homologous DNA should

be detectable in all types. Plasmid pTi-B6-806 was mapped and the T-DNA, the region of this plasmid that is maintained in the E9 tobacco tumor, was located. DNA hybridization studies were conducted to test this region of pTi-B6-806 for homology with six representative Ti plasmids. PTi-B6-806 DNA fragments to be used as probes were isolated after preparative agarose gel electrophoresis of plasmid DNA digests and labelled by the nick translation reaction. Four of the six probes hybridized with all of the Ti plasmids examined and, therefore, they must constitute a region of DNA common to all. This region extends on the map from *Sma*I fragment 17 to *Hpa*I fragment 14, a region of 5.5×10^6 daltons or less. However, the results also show that a significant portion of the T-DNA of pTi-B6-806 comprises DNA sequences not common to all Ti plasmids. (26 refs)

78-6584 Homologous DNA Sequences in Different Ti-Plasmids Are Essential for Oncogenicity.

(Eng) Depicker, A. (Laboratorium voor Genetica, Rijksuniversiteit Gent, Ledeganckstraat 35, B-9000 Ghent, Belgium); Van Montagu, M.; Schell, J. *Nature* 275(5676): 150-153; 1978.

In view of the fact that different types of Ti plasmids only have a limited degree of DNA sequence homology but produce transformed plant cells with similar phenotypes, the hypothesis that at least part of the common DNA sequences would be directly and/or indirectly involved in oncogenicity was investigated. Homology between octopine and nopaline Ti plasmids was demonstrated with the use of plasmid DNA from wild-type strains of *Agrobacterium tumefaciens* (strain ACH5 was used as an example of an octopine Ti plasmid and strains C58 and K14 were used as examples of nopaline Ti plasmids). Hybridization experiments employing labeled DNA fragments showed that a specific DNA segment is common to both octopine and nopaline Ti plasmids. At least part of this common segment is involved in the oncogenic properties of the Ti plasmids, as integration of a complete P-type plasmid pRP4 into the pTi-C58 plasmid resulted in a loss of oncogenicity. Dissociation and subsequent hybridization experiments confirmed the fact the integration of pRP4 had indeed occurred in the common DNA sequence. Genetic evidence is given that the segment overlaps with the Ti plasmid DNA found in transformed plant cells. (24 refs)

78-6585 GC/MS Determination of Cytokinins in *Agrobacterium Tumefaciens* Cultures. (Eng)

Claeys, M. (Laboratorium voor Organische Chemie, R.U.G., Krijgslaan 271 [S4], B-9000 Ghent, Belgium); Messens, E.; Van Montagu, M.; Schell, J. *Fresenius Z Anal Chem* 290(2): 125-126; 1978.

Selected ion monitoring (SIM) was used to determine the cytokinins 6-(3-methyl-2-butenylamino)purine and 6-(4-hydroxy-3-methyl-trans-2-butenylamino)purine in oncogenic and nononcogenic *Agrobacterium tumefaciens* strains. The cytokinin levels were higher in the oncogenic strains. (4 refs)

78-6586 Disappearance of Patulin During Alcoholic Fermentation of Apple Juice. (Eng) Stinson, E.

(Eastern Regional Res. Center, Federal Res., Science Education Admin., U.S. Dept. Agriculture, Philadelphia, PA, 19118); Osman, S. F.; Huhtanen, C. N.; Bills, D. D. *Environ Microbiol* 36(4): 620-622; 1978.

Patulin (PL) is a carcinogenic mycotoxin produced by spoilage organisms, including *Penicillium expansum*, which infects apples. Its persistence in apple juice during fermentation was evaluated with the use of eight commercial yeast and three typical American fermentation procedures. In apple juice containing 15 mg/liter added PL, the level was reduced to $< 50 \mu\text{g/liter}$ in all but two cases (with 2 yeasts, 50 and 70 $\mu\text{g/liter}$ were found). In all cases, however, the level was reduced by $> 99\%$ during alcoholic fermentation. In unfermented samples, the level of added PL declined only 10% when the juice was stored for 2 wk, a time equivalent to that required for fermentation. French ciders have relatively high PL levels, and four factors related to harvesting and fermentation procedures are given that may account for the result. (17 refs)

78-6587 Fecal Profiles of Anaerobic Microflora of Large Bowel Cancer Patients and Patients with Nonhereditary Large Bowel Polyps. (Eng) Mastromarino, A.

(Div. Nutritional Biochemistry, Naylor Dana Inst., American Health Foundation, Valhalla, NY, 10595); Reddy, B. Wynder, E. L. *Cancer Res* 38(12): 4458-4462; 1978.

Differences in fecal bacteria profiles were studied in 7 normal controls, 13 patients with colorectal carcinoma, and 7 patients with nonhereditary large bowel polyps. Fresh fecal specimens were processed and analyzed under anaerobic conditions for bacterial growth and 7 α -dehydroxylase (7 α -cholesterol dehydrogenase (CD), and β -glucuronidase (CD) activities. Definitive identification of about 50 isolated anaerobes was based on the Gram reaction, morphology, spore test, gas-liquid chromatography, and other biochemical determinations. There were no significant differences in fecal anaerobic microflora or total aerobic counts, which suggests that taxonomic grouping of fecal bacteria is an inadequate measure of the relative risk of developing large bowel cancer. Results of the enzyme studies showed that 7 α -D and β -G activities were higher in samples from colorectal carcinoma patients and intestinal polyp patients, compared with healthy subjects, but no difference was noted in β -G activity between the three groups. It is postulated that since all subjects were on a Western diet, composition of the diet is a major factor in microbial β -G activity. (50 refs)

78-6588 Fiber in the Diet and Carcinoma. (Fre) Lambert, R.

(Service de Gastroenterologie, Hopital Edouard Herriot, F69003 Lyon, France). *Bull Cancer (Paris)* 65(1): 71-72; 1978.

The proposed relationship between dietary fiber and cancer of the colon is discussed. Dietary fiber has been defined

vegetable residue remaining after acid and alkaline hydrolysis, but this definition is not considered adequate or precise. Dietary fat and intestinal bacteria may be linked to fiber as factors in carcinogenesis. (no refs)

- 589 **Molecular Biology of Metabolic Disease: Defects in the Regulation of Enzymic Activity.** (Eng) Galton, D. J. (Diabetes and Lipid Res. Lab., St. Bartholomew's Hosp., W. Smithfield, London EC1A 7BE, England). *Enzyme* 23(4): 274-288; 1978.

The Jacob-Monod model for regulating enzyme activity was used to analyze the loss of allosteric inhibition of phosphofructokinase by citrate in lipomatosis, disorder of covalent modification of triglyceride lipase in triglyceride-storage disorder, and a defect in the repression of 3-hydroxy-3-methylglutaryl coenzyme A reductase in a new variant of familial hypercholesterolemia. The enzyme regulatory defects were compared with inborn errors of metabolism. (26 refs)

- 590 **Characterization of 7 α -Dehydroxylase in *Clostridium leptum*.** (Eng) Stellwag, E. J. (Medical College of Virginia, Virginia Commonwealth Univ., Richmond, VA 23298); Hylemon, P. B. *Am J Clin Nutr* 31(10): 1524-1527; 1978.

The distribution and enzymatic characterization of 7 α -dehydroxylase (7 α -DH) were studied in whole cells of *Clostridium leptum* as compared to other anaerobic intestinal bacteria. 7 α -DH was assayed both quantitatively and qualitatively in several species of bacteria by culturing with 7 α -chenodeoxycholic acid. 7 α -DH activity was detected in *C. leptum*, but not in 10 other *Bacteroides* species. Enzyme activity was seen over a broad pH range in *C. leptum*, with an optimum at 6.5-7.5. Addition of 0.1 mM sodium cholate to the cultures increased 7 α -DH activity six- to eight-fold during the stationary and declining growth phases. 2,4-Dinitrophenol (0.01, 0.1, or 1 mM), carbonylcyanide-m-chlorobenzylhydrazine (1 mM), and dicyclohexylcarbodiimide (0.2 mM) strongly inhibited 7 α -DH activity, whereas 2-N-heptyl-6-hydroxyquinoline-N-oxide (1 mM) did not. It is hypothesized that 7 α -DH is found only in a restricted population of intestinal bacteria, regulated by primary bile acid concentration; under certain conditions such as diet or disease including colon cancer, total fecal bile acids and 7 α -DH activity are both noted to be high. (20 refs)

- 591 **Increased Sialylation of Surface Glycopeptides of Human Trophoblast Compared with Fetal Cells from the Same Conceptus.** (Eng) Whyte, A. (Dept. Paediatrics, Univ. Cambridge, Cambridge, England); Loke, Y. *Exp Med* 148(4): 1087-1092; 1978.

The surface glycopeptides of human trophoblastic cells were compared with those of other fetal cells from the same embryos using double-labeling methods with isotopes of

L-fucose and D-glucosamine. (The human trophoblast shows some of the features commonly associated with neoplasia, including cellular proliferation and localized invasion.) A faster-eluting neuraminidase-sensitive fraction was observed upon Sephadex chromatography of the trophoblasts when D-glucosamine was used as the precursor. Labeling with fucose did not appear to result in the differences, which suggests that the glycopeptides characteristic of trophoblasts contained glucosamine-derived metabolic products, including sialic acid but excluding fucose. This increased sialylation is similar to, but not identical with, modifications observed in neoplastic cells. It is postulated that two species of glycopeptides may be involved in atypical cellular behavior: one contains sialic acid and other sugars excluding fucose and is associated with localized cellular growth and invasion, and the other contains both sialic acid and fucose and is characteristic of neoplastic cells. (14 refs)

- 78-6592 **Retinol Induces Density-dependent Growth Inhibition and Changes in Glycolipids and LETS.** (Eng) Patt, L. M. (Biochemical Oncology, Fred Hutchinson Cancer Res. Center, Seattle, WA, 98104); Itaya, K.; Hakomori, S. *Nature* 273(5661): 379-381; 1978.

The effect of retinol on cell growth behavior, glycolipid synthesis, and surface-exposed profile of glycoproteins in NIL and NILpy hamster fibroblasts and BALB/c 3T3 mouse cells was examined. Culturing of these cells in irradiated fetal calf serum containing retinol (20 nanomoles/ml) enhanced contact orientation and density-dependent inhibition of cell growth. Associated changes in cell-surface membrane GM₁ level, ganglioside contact response, and in large, external, transformation-sensitive protein (LETS protein) were also observed. Culturing of these cells in UV-irradiated vitamin A-free medium reduced contact orientation and density-dependent inhibition of cell growth. The ability of vitamin A compounds to prevent carcinogenesis could be related to the changes in surface membrane glycolipids and glycoproteins described. However, the glycosyltransferase levels for the synthesis of hematoside in NIL cells grown in medium supplemented with retinol did not differ significantly from those in cells grown in normal medium. Thus, the biochemical basis for the effect on glycolipid synthesis and surface-labeled glycoproteins could be a more complex matter. (17 refs)

- 78-6593 **Dimeric and High Molecular Weight Forms of the Large External Transformation-sensitive Protein on the Surface of Chick Embryo Fibroblasts.** (Eng) McConnell, M. R. (Dept. Pharmacology, Harvard Medical Sch., Boston, MA, 02115); Blumberg, P. M.; Rossow, P. W. *J Biol Chem* 253(20): 7522-7530; 1978.

The subunit structure of the large external transformation-sensitive (LETS) protein of chick embryo fibroblasts was examined. When cells were labeled by lactoperoxidase-catalyzed iodination and analyzed on sodium dodecyl sulfate-polyacrylamide gels in the absence of a reducing agent, no more than 1% of the ¹²⁵I-labeled LETS protein migrated

as a monomer (mol wt: 230,000-240,000). About 20%-23% of LETS migrated as a dimer. The remaining LETS was present as a high-mol-wt (HMW) complex retained at the top of the gel. These proportions did not appear to be an artifact resulting from disulfide bond formation induced by the lactoperoxidase labeling technique. The possibility that the LETS HMW complex was actually LETS dimer that was retained at the top of the gel by trapping was also ruled out. Pulse-labeling experiments demonstrated the conversion of LETS dimer to a HMW complex. The kinetics were biphasic, with rapid conversion of most of the LETS dimer followed by slow conversion of the remainder. The proportion of LETS present as a dimer predicted from the kinetic parameters agreed well with the experimental value determined by lactoperoxidase labeling. LETS dimer and the HMW complex were shed into the medium at similar slow rates; culture conditions seemed to have little influence on the subunit structure of LETS. The significance of the LETS subunit structure for its biological activity remains to be determined. (45 refs)

78-6594 Calcitonin Heterogeneity in Lung Cancer and Medullary Thyroid Cancer. (Eng) Becker, K. L. (Veterans Admin. Hosp., Washington, DC); Snider, R. H.; Silva, O. L.; Moore, C. F. *Acta Endocrinol (Kbh)* 89(1): 89-99; 1978.

To determine whether there is an appreciable difference between the immunoreactive forms (iCT) of human calcitonin in bronchogenic cancer (BGC) and medullary thyroid cancer (MTC), the immunochemical heterogeneity of this hormone was compared in patients with these neoplasms. The sera of 7 MCT patients and 15 BGC patients were analyzed by radioimmunoassay, gel filtration, and region-specific antisera. The serum of the MCT patients contained seven iCT fractions ranging in mol wt from $\geq 30,000$ to 2,500. In contrast, $> 80\%$ of the BGC patients had predominantly high-mol-wt iCT fractions ($\geq 30,000$ and 14,600) in their sera. Following in vitro incubation of the BGC serum at 25 C for 24 hr, the high-mol-wt fractions were converted to a heterogeneous pattern similar to that of MCT serum. Furthermore, in vitro incubation in normal human serum of the high-mol-wt fractions from MTC serum resulted in their degradation to fractions of lower mol wt. In view of the larger amounts of high-mol-wt fractions in the BGC sera and the greater recognition of these fractions by midportion antisera than by carboxyl terminal antisera, it was possible to differentiate, preoperatively, between the hypercalcitonemia of the two patient groups by comparing the midportion of carboxyl terminal ratio of serum iCT levels. Only 1/15 BGC patients had a ratio similar to that encountered with the MTC patients. (21 refs)

78-6595 Spontaneous Hepatomas in Mice Inbred from Ha:ICR Swiss Stock of Sex, Cedar Shaving in Bedding, and Immunization with Fetal Liver or Hepatoma Cells. (Eng) Jacobs, B. B. (American Medical Center Cancer Res. Center and Hosp., Lakewood, CO, 80214); Dieter, D. K. *J Natl Cancer Inst* 61(6): 1531-1534; 1978.

Spontaneous tumor development was compared in Ha: Swiss mice inbred (IB) by mating brother x sister for 2 generations (designated SWJ/Jac) and noninbred (NIB) of the same strain. A total of 350 NIB females (mean age 12 mo) were autopsied, and the following tumors were noted: hepatomas (5), hemangioendotheliomas (4), lymphoid tumors (75), breast tumors (15), lung tumors (104), pituitary tumors (58), thyroid tumors (6), and adrenal tumors (1). When 130 female SWJ/Jac mice (33 retired breeders and 97 virgins) were autopsied at age 12-24 mo, tumor incidence was as follows: hepatomas (9), hemangioendotheliomas (1), lymphoid tumors (36), breast tumors (5), lung tumors (1) and pituitary tumors (1). Tumors found in 86 SWJ/Jac mice autopsied at a mean age of 21.1 mo included hepatomas (1), hemangioendotheliomas (5), lymphoid tumors (9), and pituitary tumors (17). No other tumors were seen. The hepatomas in this group were often multifocal; their high incidence was due to the presence of cedar shavings in the animals' bedding. Treatment of 3-mo-old inbred males with crude extract of spontaneous hepatomas or fetal liver did not protect them from hepatoma development. An interesting result of this experiment was the propensity of inbred males to develop hepatomas (62.8% of animals). (12 refs)

78-6596 Studies on the Culture of Human Cancer Cell Lines and Their Production of Carcinoembryonic Antigen (CEA). (Jpn) Kaneko, Y. (First Dept. Surgery, Kagoshima Univ. Sch. Medicine, Kagoshima, Japan). *Igaku Kenkyu* 48(4): 298-321; 1978.

Three rectal adenocarcinoma cell lines (CaR-1, CaR-2, and CaR-3) were derived from poorly differentiated human rectal adenocarcinoma specimens, and their production of carcinoembryonic antigen (CEA) was investigated. The cells formed a monolayered sheet and attached firmly to the inner surface of culture vessels. Morphologically, they showed few tubular patterns and suggested signet ring cells. Electron microscopy revealed epitheliallike cells with microvilli, desmosomes, interdigitations, and mucinous granules. Doubling time of the three cell lines was 46, 48, and 120 hr, respectively, and their respective modal chromosome numbers were 64, 63, and 64. Histological findings of developed tumors in nude mice, following serial heterologous transplantation, revealed similar patterns as those in primary tumors, i.e., poorly differentiated adenocarcinoma. Metastatic lymph nodes were then explanted to nude mice, and resulting tumors were cultured in vitro. Inoculum from these tumors did not differ from cells taken directly from the original tumor. Small amounts of CEA were demonstrated in the culture medium of lines CaR-1 and CaR-2 and large amounts in line CaR-3. Synthesis of CEA did not change for almost 10-30 serial passages. Changing the culture medium and adding cyclic AMP and dibutyryl cyclic AMP to the medium of CaR-1 and CaR-2 cells did not affect CEA production. Electron microscopy of the high-CEA-producing CaR-3 cells showed well-developed microvilli, glycocalyx, and microvesicles. (87 refs)

597 Growth and Transplantability of Clonally Related Tumorigenic Murine Cell Lines. (Eng) Ker, J. R. (Univ. Warwick, Dept. Biological Sciences, Coventry CV4 7AL, England). *Br J Cancer* 38(4): 513-520; 1978.

In vivo and in vitro growth properties of eight cloned lines derived from a transplantable adenovirus 12-induced CBA mouse tumor cell line, were investigated. All lines were hyperdiploid, with modal numbers of 43 to 48 chromosomes. Metacentric markers were usually present in two or three copies per cell. Polyploidy, assessed separately, was 3%-10% in all clones. Although colony morphology differed markedly between clones, cells within a clone were homomorphic. In vitro, clone doubling times ranged from 24 to 45.4 hr and saturation densities from 31 to 111×10^4 /cm². In their response to the cytotoxic effects of concanavalin A at different concentrations, the clones demonstrated three modes of growth that were unrelated to their origin in vivo. Tumorigenicity, measured by the average number of cells required to produce tumors in 50% of injectable sites (TD₅₀), ranged from 2.5×10^4 cells to 6.3×10^5 cells. Mean latent period to palpable tumor development was 6.8 wk, and the volume doubling of established tumors was 109.4 hr. A high correlation was noted between doubling times in vivo and in vitro, but no correlation was demonstrated between in vitro growth characteristics or morphology and tumorigenicity in vivo. (22 refs)

598 The Growth of the EMT6 Tumour in the Lungs of BALB C Mice Following Intravenous Inoculation of Tumour Cells from Culture. (Eng) Twentyman, P. (Dept. Radiology, Stanford Univ. Medical Center, Stanford, CA, 94305). *Cell Tissue Kinet* 11(1): 57-68; 1978.

Growth of the EMT6 tumor in the lungs of Balb C mice was studied following iv inoculation of different numbers of tumor cells. Cell suspensions were prepared from explants of lungs and the number of in vitro colony forming cells was determined by plating into petri dishes. Following iv injection of 10^4 cells, the population doubling time of clonogenic tumor cells appearing in the cell suspension was 17.2 hr until such that the total tumor cell population per set of lungs reached 10^6 cells (10-12 days). Applying correction factors for changes in ability to extract cells from the lungs into the suspension at various times and also for possible changes in plating efficiency in vitro, the doubling time ranged from 20 to 24 hr. After reaching a total size of 10^6 tumor cells, the population doubling time of clonogenic tumor cells in the lungs increased. During the later stages of tumor growth a correlation was seen between total lung tumor wt and number of clonogenic cells present. For the final 3-4 days of initial period of rapid tumor growth, it is possible to obtain a hemocytometer count of tumor cells in the lung suspension. By plating out various numbers of tumor cells in vitro control lungs and lungs from treated animals, the effect of various treatments on the clonogenic capacity of cells from microscopic tumor foci can be determined. 78-6599 Long-Term Organ Culture of Human Uterine Endocervix. (Eng) Schurch, W. (Dept. Pathology, Univ. Maryland Sch. Medicine, Baltimore, MD, 21201); McDowell, E. M.; Trump, B. F. *Cancer Res* 38(11, part 1): 3723-3733; 1978.

A method for maintaining explants of human uterine endocervix in organ culture for 24 wk is described. The explants were obtained from 18 patients who had hysterectomies for various uterine diseases (usually myoma) and from 2 autopsies. Explants were cultured at 36.5 C according to a long-term organ culture technique using CMRL-1066 medium. The epithelium was viable for the entire time of culture, as demonstrated by ultrastructural morphology and mitotic activity. The morphology of the epithelium was near normal for 2-4 wk. In the following weeks, a slow transformation of the columnar epithelium into a metaplastic epithelium was observed, with a loss of mucus-secreting columnar cells and ciliated cells, and the appearance of layers of cuboidal and flattened epidermoid cells was observed deep in the clefts even after 24 wk in culture. Metaplasia began at the top of the papillae and ridges and extended downward into the clefts. However, in a few areas deep in the clefts, columnar cells retained evidence of mucus secretion during the duration of culture. Transformation of columnar mucous cells into cuboidal and flattened cells with epidermoid characteristics signified the development of epidermoid metaplasia. This observation was supported by ultrastructural studies, which showed mucus secretion and early keratinization in the metaplastic cells. Mitotic figures were seen under the transmission electron microscope for up to 24 wk, and all dividing cells contained mucous granules. Long-term culture of the human endocervix may represent a useful in vitro system for testing metabolic and morphological responses to potential chemical and biological carcinogens. (29 refs)

78-6600 In Vitro Culture of Human Leukemia Cells. (Eng) Dicke, K. A. (Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner, Houston, TX, 77030); Spitzer, G.; Verma, D. S.; McCredie, K. B. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 311-313; 1978.

A technique was developed for the selective in vitro growth of colonies of leukemia cells. It consists of a liquid phase of 15 hr, during which phytohemagglutinin (PHA) is used as a stimulus, before a semisolid phase of 7 days. The PHA colony-formation assay was applied to cells from patients with chronic and acute myeloid leukemia, and the results were found to correlate with clinical outcome of disease in the former and tendency to early relapse in the latter. Subject Index

tion
 Uterine Neoplasms
 Endometriosis, 78-6541
 Naphthalene, 5-Nitro-
 Ames Test
 Mutagenic Activity, 78-6254
 Cholangioma
 Carcinogenic Potential, 78-6254
 Ear Neoplasms
 Carcinoma, Epidermoid, 78-6254
 Intestinal Neoplasms
 Adenocarcinoma, 78-6254
 Kidney Neoplasms
 Carcinogenic Potential, 78-6254
 Liver Neoplasms
 Carcinogenic Potential, 78-6254
 Mammary Neoplasms, Experimental
 Carcinoma, Ductal, 78-6254
 Rhabdomyosarcoma
 Carcinogenic Potential, 78-6254
 Aldehyde
 Chromatids
 Lymphocytes, 78-6188
 Chromosomes
 Mutagenic Activity, 78-6188
 DNA
 Chromosomes, 78-6188
 Cross-Linking Activity, 78-6188
 Aldehyde, Bromo-
 Ethane, 1,2-Dibromo-
 Carcinogenic Metabolite, 78-6115
 Aldehyde, Chloro-
 Deoxyribonucleosides
 Imidazo-Cyclization Products, 78-6112
 DNA
 Liver, Rat, 78-6112
 Amide, *N*-(5-*p*-Acetamidophenylthiophen-2-yl)-
 Ames Test
 Mutagenic Activity, 78-6260
 Cells, Cultured
 Cell Transformation, Neoplastic, 78-6260
 Amide, *N*-(Acetyloxy)-*N*-fluoren-2-yl-
 Chromatin
 DNA Repair, 78-6191
 DNA Repair
 Deoxyribonuclease, 78-6191
Escherichia coli
 DNA Repair, 78-6308
 Fibroblasts
 DNA Repair, 78-6191
 12-*O*-Tetradecanoylphorbol-13-acetate
 DNA Repair, 78-6308
 Virus, Feline Sarcoma
 Reverse Transcriptase, 78-6440
 Virus Replication, 78-6440
 Virus, SV40
 Cell Transformation, Neoplastic, 78-6242
 Xeroderma Pigmentosum
 DNA Repair, Review, 78-6055

Acetamide, *N*-Fluoren-2-yl-
 Carcinogenic Metabolite
 Quantitation Method, 78-6190
 Cholesterol
 Metabolism, Liver, 78-6192
 Chromosome Aberrations
 Micronucleus Test, 78-6162
 Glutamyl Transpeptidase
 Hepatocyte, Rat, 78-6492
 Hepatocytes
 Cytotoxicity, Fibroblasts, 78-6267
 Liver Neoplasms
 Barbituric Acid, 5-Ethyl-5-phenyl-, 78-6193
 Precancerous Conditions, 78-6492
 Quinone Reductases
 Liver, Rat, 78-6334
 Sulfate Derivative
 Proteins, Binding, 78-6291
 Transplantation, Homologous
 Hepatocyte, Rat, 78-6492
 Acetamide, *N*-Fluoren-4-yl-
 Hepatocytes
 Cytotoxicity, Fibroblasts, 78-6267
 Acetamide, *N*-(5-Phenylthiophen-2-yl)-
 Ames Test
 Mutagenic Activity, 78-6260
 Cells, Cultured
 Cell Transformation, Neoplastic, 78-6260
 Acetamide, Thio-
 DNA Repair
 Liver, Rat, 78-6216
 Estradiol, 3-Benzate
 Ovalbumin, 78-6347
 Progesterone, 78-6347
 Ovalbumin
 Plasma Levels, Chick, 78-6347
 Progesterone
 Plasma Levels, Chick, 78-6347
 Acetanilide
 Lymphocytes
 Aryl Hydrocarbon Hydroxylases, 78-6292
 Plasma
 Half-Life, 78-6292
 Acetanilide, 4'-Hydroxy-
 Microsomes, Liver
 Metabolism, 78-6291
 Acetic Acid, (4-Chloro-2-methylphenoxy)-
 see Acetic Acid, ((4-Chloro-*o*-tolyl)oxy)-
 Acetic Acid, ((4-Chloro-*o*-tolyl)oxy)-
 Saccharomyces cerevisiae
 Mutagenic Activity, 78-6287
 Acetic Acid, (2,4-Dichlorophenoxy)-
 Cells, Cultured
 Metabolism, Lung, 78-6305
 Mutagenic Activity
 Blue-Green Algae, 78-6271
 Saccharomyces cerevisiae
 Mutagenic Activity, 78-6287
 Sarcoma
 Occupational Hazard, 78-6288

- Acetic Acid, (Ethylenebis(oxyethylenenitrilo))tetra-**
Lymphoma
Rosette Formation, AKR Mouse, 78-6503
Thymoma
Rosette Formation, AKR Mouse, 78-6503
- Acetic Acid, (2,4,5-Trichlorophenoxy)-**
Cells, Cultured
Metabolism, Lung, 78-6305
Saccharomyces cerevisiae
Mutagenic Activity, 78-6287
Sarcoma
Dibenzo-*p*-dioxin, 2,3,7,8-Tetrachloro-, 78-6288
Occupational Hazard, 78-6288
- p*-Acetophenetidide, *N*-Hydroxy-**
Glucuronate Derivative
Proteins, Binding, 78-6291
Microsomes, Liver
Metabolism, 78-6291
Quinone, *N*-Acetylimido-
Sulfate Derivative, 78-6291
Sulfate Derivative
Proteins, Binding, 78-6291
- p*-Acetophenetidide**
Immunosuppression
Carcinogenic Activity, Review, 78-6051
Kidney Neoplasms
Carcinoma, Transitional Cell, 78-6293
Case Report, 78-6293
Lymphocytes
Aryl Hydrocarbon Hydroxylases, 78-6292
Microsomes, Liver
Metabolism, 78-6291
Plasma
Half-Life, 78-6292
- Acetophenone**
Smoke Condensate
Isolation and Characterization, 78-6171
- Acetophenone, 2-Amino-**
Leukemia
Species Difference, 78-6202
- Acetylglucosaminidase**
Benzene
Enzymatic Activity, Rat, 78-6258
Granulocytes, 78-6258
Lymphocytes, 78-6258
- Acetyltransferases**
Benzenamine, 4,4'-Methylenebis-(2-chloro)-
Acetylation Kinetics, 78-6264
Benzidine
Acetylation Kinetics, 78-6264
Fluoren-2-amine
Acetylation Kinetics, 78-6264
Isonicotinic Acid Hydrazide
Acetylation Kinetics, 78-6264
1-Naphthylamine
Acetylation Kinetics, 78-6264
2-Naphthylamine
Acetylation Kinetics, 78-6264
Sulfanilamide, *N*-(4,6-Dimethyl-2-pyrimidinyl)-
Acetylation Kinetics, 78-6264
- Achlorhydria**
Stomach Neoplasms
Gastritis, 78-6533
- Acridinium, 3,6-Diamino-10-methyl-, Chloride**
Escherichia coli
Mutagenic Activity, 78-6159
Mutagenic Activity
Galactose Resistance, 78-6159
Salmonella typhimurium
Mutagenic Activity, 78-6159
- Acriflavine**
see Acridinium, 3,6-Diamino-10-methyl-, Chloride
- Acrylamide, 2-(2-Furyl)-3-(5-nitro-2-furyl)-**
Enzyme Activation
Microsomes, Testis, 78-6227
Escherichia coli
Enzyme Activation, 78-6227
Oxidoreductases
Microsomes, Testis, 78-6227
Saccharomyces cerevisiae
Growth, Radiation-Sensitive Mutants, 78-6244
- Acrylonitrile**
Occupational Hazard
Carcinogenic Activity, Review, 78-6021
Exposure Standards, Review, 78-6021
- Actinomycin D**
Estradiol, 3-Benzoyl
Ovalbumin, 78-6347
Progesterone, 78-6347
Ovalbumin
Plasma Levels, Chick, 78-6347
Progesterone
Plasma Levels, Chick, 78-6347
Saccharomyces cerevisiae
Mutagenic Activity, 78-6304
- Adenine**
Aflatoxin B1
DNA Cleavage, 78-6124
- Adenine, 3-Methyl-**
Dimethylamine, *N*-Nitroso-
DNA, 78-6215
Urea, Methyl Nitroso-, 78-6215
Urea, Methyl Nitroso-
Chromatin, Liver, 78-6215
- Adenocarcinoma**
Bladder Neoplasms
Epidemiology, 78-6567
Cecal Neoplasms
Benzenamine, 2-Methyl-4-((2-methylphenyl)azo)-
78-6286
Cholanthrene, 3-Methyl-, 78-6321
Colonic Neoplasms
4-Biphenylamine, 3,2'-Dimethyl-, 78-6297
Cholanthrene, 3-Methyl-, 78-6321
Colitis, Ulcerative, 78-6537
Genetics, 78-6538
Ultrastructural Study, 78-6536
Intestinal Neoplasms
Acenaphthene, 5-Nitro-, 78-6254
Radiation, Ionizing, 78-6385
Schistosoma japonicum, 78-6535
Kidney Neoplasms
Radium, 78-6564
Ultrastructural Study, 78-6532
Lung Neoplasms
Asbestos, 78-6168
Epidemiology, 78-6547

nocarcinoma (cont'd)

- Mammary Neoplasms, Experimental
 - 4-Biphenylamine, 3,2'-Dimethyl-, 78-6297
 - Phagocytosis, 78-6526
 - Radiation, Ionizing, 78-6050
 - Selenium, 78-6146
 - 4,4'-Stilbenediol, α,α' -Diethyl-, 78-6342
- Nose Neoplasms
 - Reverse Transcriptase, 78-6521
 - Ultrastructural Study, Sheep, 78-6521
 - Virus-Like Particles, 78-6521
- Prostatic Neoplasms
 - Virus, Cytomegalo, 78-6499
- Radiation, Ionizing
 - 1*H*-Imidazole-1-ethanol, α -(Methoxymethyl)-2-nitro-, 78-6385
- Rectal Neoplasms
 - Carcinoembryonic Antigen, 78-6596
 - Radiation, Ionizing, 78-6385
 - Transplantation, Heterologous, 78-6596
 - Ultrastructural Study, 78-6596
- Stomach Neoplasms
 - Agammaglobulinemia, 78-6534
 - Anemia, Pernicious, 78-6534
 - Gastritis, 78-6534
 - Immunologic Deficiency Syndromes, 78-6534
 - Plants, Edible, 78-6210
- Thyroid Neoplasms
 - Epidemiology, 78-6523
 - Radiation, Ionizing, 78-6378, 78-6523
 - Radiotherapy, 78-6380
- Uterine Neoplasms
 - Epidemiology, Review, 78-6026

nocarcinoma, Papillary

- Mammary Neoplasms, Experimental
 - Benz(a)anthracene, 7,12-Dimethyl-, 78-6315
- Thyroid Neoplasms
 - Radiation, Ionizing, 78-6363, 78-6377

enofibroma

- Breast Neoplasms
 - Antibodies, Viral, 78-6412
 - Precancerous Conditions, 78-6553
- Mammary Neoplasms, Experimental
 - Radiation, Ionizing, 78-6050, 78-6342
 - Xanthine, 3-Hydroxy-, 78-6250

enoma

- Cecal Neoplasms
 - Benzenamine, 2-Methyl-4-((2-methylphenyl)azo)-78-6286
- Colonic Neoplasms
 - Ultrastructural Study, 78-6536
- Gynecologic Neoplasms
 - 4,4'-Stilbenediol, α,α' -Diethyl-, 78-6027
 - Transplacental Carcinogenesis, Review, 78-6027
- Liver Neoplasms
 - Carcinoembryonic Antigen, 78-6352
 - Contraceptives, Oral, 78-6352, 78-6354
 - Estrogens, 78-6352
- Lung Neoplasms
 - Carbamic Acid, Ethyl Ester, 78-6185
 - Carbamic Acid, Vinyl Ester, 78-6185
 - Xanthine, 3-Hydroxy-, 78-6249
- Mammary Neoplasms, Experimental
 - Xanthine, 3-Hydroxy-, 78-6250
- Pancreatic Neoplasms
 - Streptozotocin, 78-6208

Adenoma (cont'd)

- Parathyroid Neoplasms
 - Epidemiology, 78-6379
 - Radiation, Ionizing, 78-6376, 78-6377, 78-6379
- Thyroid Neoplasms
 - Imidazole-2-thiol, 1-Methyl-, 78-6248
 - Radiation, Ionizing, 78-6523

Adenosine Cyclic 3',5' Monophosphate

- Erythroleukemia
 - Caffeine, 78-6426
 - Cell Differentiation, 78-6426
 - 2-Imidazolidinone, 4-Methoxy-, 78-6426
 - Theophylline, 78-6426
 - Virus, Friend Murine Leukemia, 78-6426
 - Xanthine, 3-Isobutyl-1-methyl-, 78-6426
- Rectal Neoplasms
 - Carcinoembryonic Antigen, 78-6596
- Retinoic Acid
 - Plasminogen Activators, 78-6338
- 12-*O*-Tetradecanoylphorbol-13-acetate
 - Plasminogen Activators, 78-6338
- Virus, Rous Sarcoma
 - Plasminogen Activators, 78-6338

Adrenal Gland Neoplasms

- Epidemiology
 - Inbred Mice, 78-6595
- Kidney Neoplasms
 - Radiotherapy, 78-6384
- Radiation, Ionizing
 - In Utero Exposure, Rat, 78-6382

Adriamycin

- Antineoplastic Agents
 - Ames Test, 78-6232
- Escherichia coli*
 - DNA Repair, 78-6308

Aflatoxin B1

- Adenine
 - DNA Cleavage, 78-6124
- Aflatoxin M1
 - Metabolism, Rat, 78-6125
- Cell Transformation, Neoplastic
 - Diploid Cells, 78-6245
- Cells, Cultured
 - Colony Formation, Agar, 78-6245
- DNA Repair
 - Liver, Rat, 78-6216
- Guanine
 - DNA Cleavage, 78-6124
- Mesenchymoma
 - Cells, Cultured, 78-6245
- Microsomes, Liver
 - DNA Degradation, 78-6124
- Piperidine
 - DNA Cleavage, 78-6124
- Virus, Feline Sarcoma
 - Reverse Transcriptase, 78-6440
 - Virus Replication, 78-6440
- Virus, SV40
 - Cell Transformation, Neoplastic, 78-6242

Aflatoxin M1

- Aflatoxin B1
 - Metabolism, Rat, 78-6125
- Starch
 - Hepatotoxicity, 78-6125
 - Metabolism, Rat, 78-6125

Aflatoxin M1 (cont'd)

- Sucrose
- Metabolism, Rat, 78-6125

Agammaglobulinemia

- Stomach Neoplasms
- Adenocarcinoma, 78-6534

Agrobacterium tumefaciens

- Cytokinins
- Isolation and Characterization, 78-6585
- DNA, Bacterial
- Carcinogenic Activity, 78-6584
- DNA-DNA Hybridization, 78-6583, 78-6584
- Plasmids, 78-6583, 78-6584
- Endonucleases
- DNA, Mobility, 78-6582
- Isolation and Characterization, 78-6582
- Isomerases
- Isolation and Characterization, 78-6582
- Plant Tumors
- DNA, Bacterial, 78-6583
- Plasmids
- Cytokinins, 78-6585
- Purine, 5-(4-Hydroxy-3-methyl-*trans*-2-butenylamino)-
- Isolation and Characterization, 78-6585
- Purine, 6-(3-Methyl-2-butenylamino)-
- Isolation and Characterization, 78-6585

Air Pollution

- Activity Cycles
- Health Effects, 78-6156
- Carbon Radioisotopes
- Dose-Response Study, 78-6386
- Nuclear Power, 78-6386
- Carcinogen, Chemical
- Dose-Response Study, 78-6110
- Circadian Rhythm
- Health Effects, 78-6156
- Ethylene, Chloro-
- Dose-Response Study, 78-6110
- Lead
- Body Burden, Child, 78-6136
- Chromosome Aberrations, 78-6136
- Cytogenetic/Biochemical Effect, 78-6135
- Lung Neoplasms
- Carbon Dioxide, 78-6019
- Fossil Fuels, Review, 78-6019

Alanine Aminotransferase

- Benzidine, 3,3'-Dichloro-
- Enzymatic Activity, Dog, 78-6270
- Chloroform
- Hepatotoxicity, Rat, 78-6109

Alanine, 3-(*p*-(Bis(2-chloroethyl)amino)phenyl)-

- Immunosuppression
- Carcinogenic Activity, Review, 78-6051

Alanine, Phenyl-

- Ames Test
- Pyrolysis Product, 78-6201

Alcohol Oxidoreductases

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations or citations of significant carcinogenesis articles collected from the current major biomedical sources of world literature. This service is provided by the National Cancer Institute through a contract with the Franklin Research Center for preparation of the publication, under Contract No. NOI-CP-75885 with the National Cancer Institute, U.S. Department of Health, Education and Welfare. Published and distributed by the Franklin Institute PressSM.

SUBSCRIPTIONS

Published by The Franklin Institute Press, Box 2266, Philadelphia, PA 19103. Subscription rate for Volume 16, consisting of 12 monthly issues and a cumulative index is \$75.00, Domestic and \$90.00, Foreign. Check should be made payable to The Franklin Institute Press.
The Franklin Institute Press Co., Ltd., 3-10, Nihonbashi 2-Chome, Tokyo 103, Japan, is the exclusive distributor of CARCINOGENESIS ABSTRACTS in Japan.

1871-1872

GENERAL INFORMATION

CARCINOGENESIS ABSTRACTS makes available abstracts, annotations, or citations of significant cancer articles collected from the current major biomedical sources of the world literature. This service is provided by the National Cancer Institute through a contract with Franklin Research Center for preparation of the publication.

FREQUENCY OF PUBLICATION: *CARCINOGENESIS ABSTRACTS*, Volume 16, is published in 12 monthly issues with indexes, plus a cumulative index.

ABBREVIATIONS

JOURNAL names are abbreviated according to the *List of Journals Indexed in Index Medicus, Abbreviation Listing*. If the journal is not listed in this, abbreviations are derived from the *International List of Periodical Title Word Abbreviations*.

LANGUAGE of the article is indicated in parentheses after the title and is represented by a three-letter code. The source for these codes is *MARC Manuals Used by the Library of Congress*, pages 183-187.

ABBREVIATIONS used in abstracts:

A	angstrom(s)	mOsm	milliosmolar
ACTH	adrenocorticotrophic hormone	max	maximum
ADP	adenosine diphosphate	mEq	milliequivalent(s)
AMP	adenosine monophosphate	min	minute(s)
ATP	adenosine triphosphate	ml	milliliter(s)
approx	approximately	μl	microliter(s)
av	average	mm	millimeter(s)
BCG	bacillus Calmette-Guerin	mo	month(s)
bid	twice daily	mol wt	molecular weight
C	degree(s) centigrade	N	normal concentration
cal	calorie(s)	NAD	nicotinamide adenine dinucleotide
kcal	kilocalorie(s)	NADH	reduced nicotinamide adenine dinucleotide
cc	cubic centimeter(s)	NADP	nicotinamide adenine dinucleotidephosphate
Ci	curie(s)	NADPH	reduced nicotinamide adenine dinucleotidephosphate
mCi	millicurie(s)	NCI	National Cancer Institute
μCi	microcurie(s)	NIH	National Institutes of Health
cm	centimeter(s)	PAS	periodic acid-Schiff
CNS	central nervous system	po	orally
cpm	counts per minute	ppb	parts per billion
DNA	deoxyribonucleic acid	ppm	parts per million
ED ₅₀	median effective dose	qid	four times daily
EDTA	ethylenediamine tetraacetic acid	qod	every other day
g	gram(s)	QO ₂	oxygen quotient
kg	kilogram(s)	R	roentgen
mg	milligram(s)	RBC	red blood cells (erythrocytes)
μg	microgram(s)	RNA	ribonucleic acid
Hb	hemoglobin	rpm	revolutions per minute
hr	hour(s)	sc	subcutaneous
ia	intra-arterial	sec	second(s)
id	intra-dermal	SGOT	serum glutamic-oxaloacetic transaminase
gA	Immunoglobulin A	SGPT	serum glutamic-pyruvic transaminase
gB	Immunoglobulin B	soln	solution
gG	Immunoglobulin G	TCD	tissue culture dose
gM	Immunoglobulin M	TCD ₅₀	median tissue culture dose
LS	increased life span	tid	three times daily
m	intramuscular	UV	ultraviolet
p	intraperitoneal	WBC	white blood cells (leukocytes)
U	International Unit(s)	wk	week(s)
v	intravenous	wt	weight
km	Michaelis constant	X	times
.D	lethal dose	yr	year(s)
.D ₅₀	median lethal dose		
M	molar		
μM	micromolar

REVIEW

601 Screening Techniques for Identification of Carcinogens: An Overview. (Eng) Magee, P. N. Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, (19140). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 404 pp.; 1935-1942; 1978.

ough none of the current screening techniques for identifying chemical carcinogens are sufficiently far developed to replace conventional long-term animal studies, several show promise. Among the screening procedures reviewed are those for carcinogenesis, precarcinogenesis, in vitro transformation or mutagenesis as end points and those that depend on specific indirect effects of carcinogens. (36 refs.)

602 Mutation and Latency in Carcinogenesis. (Eng) Knudson, A. G. (Inst. Cancer Res., 7701 Burdette Ave., Philadelphia, PA, 19111). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 209-225; 1977.

ent evidence relating somatic mutation and the phenomenon of latency to the origin of cancer is reviewed. A significant fraction of human cancer seems to involve somatic mutation. The chromosomal abnormalities observed in most cancers may in some instances represent this mutation, but in most cases these abnormalities are probably the result rather than the cause. Many environmental carcinogens increase spontaneous mutation rates that give rise to background cancer incidence. Some genetic disorders predispose an individual to environmentally induced carcinogenesis, and others create a high probability of the occurrence of site-specific cancers, even in the apparent absence of environmental carcinogens. The infrequent occurrence of neoplastic transformation of cells in the latter individuals suggests that another factor is required. So also do the phenomena of latency and dependence of cancer incidence. It is proposed that a carcinogen produces a first mutation in some cells, one of which then acquires a second mutation, which might be spontaneous or induced. When the first mutation is inherited, as in dominantly inherited predispositions, an environmental carcinogen would be expected to supply the second mutation. In this case, the latent period between exposure and clinically

apparent tumor should be reduced. The most satisfactory explanation for the age-dependence phenomenon is that the target cells for transformation are embryonal cells that differentiate and cease dividing. Any cancer mutations that occur after differentiation cannot be expressed. The age-specific incidence curves observed for the hereditary forms of these tumors directly reflect the median elapsed time for the occurrence of a second mutation, since the first mutation is present at the time of fertilization. This time is thus similar to the latent period observed following acute exposure to a carcinogen. (40 refs.)

78-6603 Hormonal Control of Tumor Growth. (Eng) Jensen, E. V. (Ben May Lab. Cancer Res., Univ. Chicago, Chicago, IL, 60637). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 209-225; 1977.

The relationship between steroid hormone receptors and the dependence of cancer of the breast and prostate gland on endocrine support is reviewed. Malignant tissues that depend on steroid hormones for their growth and function have a high level of receptor proteins with which the hormones combine to exert their biological effects. Some malignant neoplasms derived from hormone-dependent tissue retain the hormone dependence of the parent tissue, but others escape from hormonal control. Most hormone-dependent breast tumors can be distinguished from autonomous cancers by measuring their estrogen-receptor (estrophilin) levels. Because not all receptor-containing breast cancers are hormone-dependent, it appears that, in the case of neoplastic cells, the coupling between the synthesis of receptor protein and the need for hormonal stimulation in the nucleus is not as precise as it appears to be in normal tissues. Estrophilin levels can predict hormone dependence correctly in 85%-90% of breast cancer patients, but the fundamental criterion of hormone dependence appears to reside in the nucleus, where a simple test for susceptibility of the RNA polymerase system to stimulation by an estrogen-receptor complex might provide a more precise identification of responsive and nonresponsive cancers. Use of the progesterone receptor as a marker for the functionality of estrogen receptor in cancer cells is being evaluated. (33 refs.)

78-6604 Overview, Fact, Myth and Speculation. (Eng) Clayson, D. B. (Eppley Cancer Inst., Univ. Ne-

braska Medical Center, Omaha, NB, 68105). *J Environ Pathol Toxicol* 2(1): 1-8; 1978.

The validity of several assumptions regarding agents that may be considered carcinogenic to humans is questioned. All but 3 of the 20-50 agents known to be effective carcinogens in humans are also carcinogenic in animals. This indicates that between 6%-15% of transspecies extrapolations from humans to animals are discordant. The alternative approach, from the 1,000-1,500 known animal carcinogens to the human situation, is not possible because significant human exposure to many of these carcinogens may not have occurred or because epidemiologic studies may not have been performed. A new definition that would distinguish a true carcinogen from an agent that modifies the expression of another carcinogen is needed. Many of the methods for distinguishing between true carcinogens and modifiers already exist, such as microbial and mammalian cell mutation assays. Problems also exist in extrapolating from high doses, represented by the maximum tolerated dose administered to animals, to the low doses to which humans are exposed. The current view that there is no threshold dose for a carcinogen may also require modification. As more is learned about the mechanism of carcinogenesis, it may be possible to define certain critical rate-limiting steps in the process and to understand more clearly the likely shape of the dose-response curve at levels too low to follow economically by animal bioassay. (20 refs.)

78-6605 Problems of Assessing the Genetic Impact of Mutagens on Man (Meeting Abstract). (Eng) Newcombe, H. B. (Biology and Health Physics Div., Atomic Energy of Canada Ltd., Chalk River, Ontario, Canada). *Can J Genet Cytol* 20(3): 451; 1978. (no refs.)

78-6606 In Vitro Assay for Tumor Promoters and Anti-promoters. (Eng) Chang, C. C. (Dept. Human Development, Coll. Human Medicine, Michigan State Univ., E. Lansing, MI, 48824); Trosko, J. E.; Warren, S. T. *J Environ Pathol Toxicol* 2(1): 43-64; 1978.

The literature relating to the two-stage theory of carcinogenesis is reviewed, and an in vitro assay for tumor promoters and anti-tumor promoters is described. The two-stage theory postulates that carcinogenesis requires an initiation step and a promotion step. It has also been postulated that mutagenesis is responsible for promotion. The two-stage phenomenon has been demonstrated in several in vitro systems designed to measure transformation and mutagenesis in carcinogen-exposed cells that were posttreated with tumor promoters. Tumor promoters and anti-tumor promoters modify the induction of ornithine decarboxylase, the production of plasminogen activator, and the recovery of induced mutations. The recovery of mutagen-induced ouabain-resistant mutations in cultured Chinese hamster cells was increased by

treatment with 12-O-tetradecanoylphorbol-13-acetate (TPA), a tumor-promoter, and decreased by treatment with caffeine, an anti-tumor promoter. This suggests that many induced mutations can be repressed or derepressed by promoters or antipromoters. TPA also increased the recovery of UV-induced 6-thioguanine-resistant mutants. The results support the hypothesis that tumor initiation is due to a mutagenic event, but tumor promotion is the result of an epigenetic process involving cyclic nucleotide modulation of gene expression. 78-6607 Microsomal Enzyme Systems and Drug Toxicities. (Eng) Gillette, J. R. (Chemical Pharmacology Lab., Natl. Heart, Lung and Blood Inst., Bethesda, MD 20014). In: *Rat Hepatic Neoplasia: Workshop on Rat Liver Neoplasia held by William F. Merrell, Co. in Woods Hole, October, 1974*. William F. Merrell, Co. (Woods Hole, MA) 288 pp.; 100-113; 1978.

Toxic compounds that are converted in the body to chemically reactive metabolites that combine irreversibly with macromolecules such as DNA, RNA, protein, and glycogen are discussed. The induction of liver necrosis by halobenzenes illustrates many of the ways by which the severity of drug-induced tissue damage can be affected by changes in the formation or fate of chemically reactive metabolites. Bromobenzene-induced liver necrosis is caused by the covalent binding of a metabolite of bromobenzene formed by a cytochrome P-450 enzyme. The dose of bromobenzene affects the proportion of the dose that is bound to liver microsomes as well as the effects of phenobarbital pretreatment. The reason for the dose effect is related to the fact that liver cells have several ways of metabolizing bromobenzene. Information about the activation of chemicals in biological systems has also derived from studies with carbon tetrachloride. Although many drugs can be converted to chemically reactive metabolites and covalently bound to microsomal protein, it is not clear to what extent the covalent binding can be used to predict the incidence of various kinds of toxicity. 78-6608 Unscheduled DNA Synthesis of Human Cells as a Short-term Assay for Chemical Carcinogens. (Eng) Stich, H. F. (Cancer Res. Centre, Univ. British Columbia, Vancouver, B.C., Canada); San, R. H.; Lam, P. Koropatnick, J.; Lo, L. In: *Human Risk Assessment. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book C), 583 pp.; 1499-1512; 1977.

The use of unscheduled DNA synthesis of human cells as a short-term assay for chemical carcinogens is explored. The extent of DNA fragmentation and repair can be estimated accurately by several methods, but the alkaline sucrose gradient technique and the unscheduled incorporation of

H-thymidine appear to be the only ones suited for large-scale testing programs. Factors affecting DNA repair levels include hyperthermia, genetics, carcinogenic and noncarcinogenic chemicals, refractory period, and species. In tests of a possible correlation between the carcinogenicity of a compound and its ability to trigger DNA repair synthesis, only 1/104 carcinogens screened were not detected by the DNA repair assay. The possibility has been raised that various cell types can be used as target cells. This would offer the opportunity to examine the activation potential of various tissues and to link this property with the action of organotropic carcinogens. The DNA repair bioassay has also been used to study the effect of two chemical carcinogens applied simultaneously or in sequence. When 4-nitroquinoline-1-oxide and N-methyl-N'-nitro-N-nitrosoguanidine were applied sequentially or simultaneously, typically, an additive effect was observed at lower concentrations, an inhibitory effect at higher concentrations. This bioassay can also be used to detect defects at various steps of the repair chain, eg, in xeroderma pigmentosum cells. The DNA fragmentation and DNA repair bioassays should yield information about the validity of applying data from animals to humans or from cultured cells to in vivo conditions. (41 refs)

In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 1977: 147-268; 1977.

Evidence surrounding the current genetic theories of cancer biology is reviewed. A number of agents, including environmental exposures of a chemical or irradiation nature in the workplace or elsewhere are known to cause genetic changes in human genomes. Viruses have been specifically implicated as being a transmissible agent in cervical cancer, Burkitt's lymphoma, nasopharyngeal cancer in the Chinese, and Hodgkin's disease early in life. These possible carcinogens may not

always act directly, but rather through intermediates arising from metabolic processes. A few cancers are known to be caused by germinal mutations, but these mutations may also only supply a predisposition to a cancer as in Xeroderma pigmentosum. Somatic mutations as well may be causative in some tumors. Most cancers are known to be karyotypically abnormal, but except for a small number of known markers (eg, the Philadelphia chromosome) these changes are not constant from tumor to tumor and may even occur differently within a single tumor. The valid question arises as to whether the observed chromosome abnormalities are the cause or the result of the tumor. The earliest origins of tumors are being intensely studied, and the glucose-6-phosphodiesterase marker system may be of value in this regard. If genetic changes are crucial to neoplastic change, it is important to learn whether these changes are always the same or whether a subset of the possible changes is sufficient to initiate neoplasia. Study must therefore be conducted in four areas: inherited genes that predispose to malignancy, integration of oncogenic virus genomes, specific chromosome alterations, and mutational events caused by the environment or some other yet unidentified factor. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 39-53; 1977.

The carcinogenic implications of environmentally induced DNA damage and its faulty repair are reviewed. Damage to cellular DNA by physical and chemical carcinogens is a ma-

major factor in environmental carcinogenesis. Living organisms possess several enzymatic mechanisms for repairing this damage. In bacteria, three basic mechanisms have been identified and partially characterized: photoenzymatic repair, excision repair, and recombination repair. Similar mechanisms are also present in mammalian systems, such as human cells in culture. However, it appears that mammalian DNA damaged in vivo is not repaired completely. This is ascribed to (1) nuclear proteins masking a fraction of the damage for repair enzymes and (2) cell differentiation during development, leading to low repair abilities among certain cell types. In general, the lower the proliferative capacity of a cell type, the lower its ability to repair. In addition, damage may be repaired inaccurately, possibly by error-prone mechanisms. Thus, due to incomplete and inaccurate repair, defects may accumulate in DNA, and it is postulated that this accumulation of genetic damage plays a key role in neoplastic transformation induced by physical and chemical carcinogens. This postulate is supported by the association between defective DNA repair and cancer-proneness in humans with certain rare hereditary disorders (eg, xeroderma pigmentosum and ataxia telangiectasia). It is hypothesized that altered DNA predisposes a somatic cell to malignant transformation either by increasing the frequency of mutations and chromosomal changes or by promoting transformation by oncogenic viruses. Although this hypothesis is supported by experimental evidence, the molecular events underlying the emergence of the malignancy remain obscure. (15 refs)

- 78-6614 Xeroderma Pigmentosum and the Role of DNA Repair in Oncogenesis.** (Eng) Giannelli, F. (Paediatric Res. Unit, Prince Philip Res. Labs., Guy's Hosp. Medical Sch., London, SE1 9RT, England). *Bull Cancer (Paris)* 65(3): 323-334; 1978.

Xeroderma pigmentosum (XP) is discussed, with particular reference to its role as a model for actinic carcinogenesis. The light sensitivity of 80%-90% of XP patients can be explained by defects in the excision repair mechanism for reversal of DNA damage (pyrimidine dimers). Measurement of release of supercoils in DNA and the consequent reduction in the density of nucleoids has shown that strand incisions (the first step in excision repair) do not occur at normal rates in XP cells. Restoration of normal rates of DNA repair in XP patients by cell fusion has led to the conclusion that there are at least five complementation groups of the disease (A to E), of which A, C, and D are the most numerous and among which racial differences may exist. Groups A and E are complemented rapidly, group C more slowly, and group D very slowly. Ten to twenty percent of XP patients, known as XP-variants, are not defective in dimer excision but in repair synthesis of excised DNA. XP cells in culture are sensitive to many different chemical carcinogens and mutagens, which indicates that the DNA repair systems defective in XP have broad specificity and that the factor defective in XP recognizes a number of different lesions and initiates their repair by excision. This potential for chemical carcinogenesis may

help explain the presence of DNA abnormalities in cells exposed to sunlight in XP patients. XP should provide a good model for the study of human actinic carcinogenesis, because XP and normal cells seem to differ in their response to light more quantitatively than qualitatively, and the phenomena of XP can be fitted to the mutational, viral, immunologic theories of cancer etiology. (81 refs)

- 78-6615 Chemical-Biological Reactions Common to Teratogenesis and Mutagenesis.** (Eng) Hasegawa, R. D. (Dept. Pharmacology, Vanderbilt Medical Center, Nashville, TN, 37232). *Environ Health Perspect* 24: 87-101; 1978.

A review of the chemical-biological interactions that are common to the mutagenic and teratogenic responses to toxic chemicals is presented. The cytotoxic agents can be grouped as alkylating agents, electrophilic reactants, antimetabolites, intercalating agents, amino acid antagonists, spindle poisons, and additional chemicals that covalently bind to DNA. Alkylating agents and electrophiles react by attacking nucleophilic areas of biological molecules. Antimetabolites inhibit pathways of purine or pyrimidine biosynthesis and formation of thymidylic acid. Nucleic acid replication is inhibited by incorporation of these compounds into nucleic acids as base analogs. Intercalating agents insert between base pairs in DNA and interfere with transcription and replication. Amino acid antagonists inhibit protein and nucleic acid synthesis by interfering with specific amino acids required for protein or nucleic acid synthesis. Specific interference with asparagine, aspartic acid, glutamine, methionine, phenylalanine, and tyrosine utilization has been reported. Spindle poisons condense with microtubular protein and interfere with formation of cellular organelles and the spindle apparatus. Miscellaneous cytotoxins covalently bind with DNA and inhibit DNA synthesis and repair. Representative examples of these classes of cytotoxic agents are given and both specific and general reactions are outlined. (115 refs.)

criteria established by the International Agency for Research on Cancer/World Health Organization ad hoc working group for evaluating the carcinogenic risk of chemicals to humans are presented. (77 refs)

78-6618 Mutations, Chromosome Aberrations and Cancer. (Eng) Bishun, N. (Tissue Culture and Cytogenetics Unit, Res. Dept., Marie Curie Memorial Foundation, The Chart, Oxted, Surrey, England); Smith, N.; Williams, D. *Clin Oncol* 4(3): 251-263; 1978.

The correlation among mutagenesis, clastogenesis, and carcinogenesis produced by many commonly used compounds (drugs, cosmetics, pesticides, food preservatives, industrial chemicals, and oral contraceptives) is summarized. The systematic screening of chemicals for mutagenicity and chromosome-breaking activity has played a significant role in establishing the fundamental points of the chromosome theory of carcinogenesis. Recently, studies have been undertaken to establish correlations between the chromosome damage produced by carcinogenic chemicals and the molecular aberrations that may be involved in the induction of carcinogenesis. A subtle correlation was found between the mutagenic selectivities and carcinogenic potential of N-acetyl-2-aminofluorene and its metabolites. Unfortunately, almost nothing is known of the molecular effects of environmental chemicals on chromosomal material. However, it does not follow that a chemical that is mutagenic and produces chromosomal abnormalities is necessarily carcinogenic, although there may be similarities in those interactions with DNA that lead to chromosomal aberrations, mutagenicity, or carcinogenicity. Thus, far from finding a close correlation between mutagenesis and cancer development, it can be concluded that almost any chemically reactive compound, if tested by a sufficiently wide range of methods, is likely to prove mutagenic in some systems. Laboratory test procedures favored for drug safety evaluation are described. (18 refs)

78-6619 DNA Damage and Repair In Vivo. (Eng) Brash, D. E. (Dept. Biophysics, Ohio State Univ., Columbus, OH, 43210); Hart, R. W. *J Environ Pathol Toxicol* 1(1): 79-114; 1978.

Evidence implicating DNA damage in carcinogenesis is briefly summarized, and in vivo methods for studying DNA adducts and excision repair and strand breaks and strand-break repair are reviewed. Induction of DNA adducts by UV light, rays, and chemical carcinogens is usually monitored through the appearance of identified products in the DNA. Chromatography or immunological detection are the usual identification techniques. DNA-protein and DNA-DNA crosslinks are assayed as changes in DNA extractability, membrane filter adsorption, melting temperature, and maturation rate. Of the five steps involved in excision repair of DNA adducts, base cleavage, excision, polymerization,

and ligation have been studied in vitro and in vivo; incision has only been studied in vitro. Single-strand breaks in cellular DNA in situ can arise from x- or γ -radiation, nicking during excision repair of chemical carcinogens or UV light, or replication past a damaged site. Induction and repair of strand breaks have been studied in vivo by alkaline sucrose gradient sedimentation, DNA polymerase initiation sites, hydroxypapatite chromatography, and S₁ nuclease digestion. Postreplication repair has not been studied in vivo, and photoreactivation of cyclobutane-type pyrimidine dimers in vivo has not been demonstrated. (209 refs)

78-6621 Theoretical Mechanisms for Synthesis of Carcinogen-induced Embryonic Proteins: III. The tRNA Methylases: Methylation Mechanism and Function. (Eng) Hancock, R. L. (High River Inst. Theoretical Cancer Study, High River, Alberta, Canada); Hancock, C. D. *Med Hypotheses* 4(5): 497-515; 1978.

It is hypothesized that redundant repressed transfer RNA (tRNA) methylase genes that are active in embryonic states can be derepressed (induced) with carcinogens in adult cells. Supportive evidence, especially from molecular model building, is presented for a mechanism of tRNA methylation. In this mechanism, the adenine moiety of S-adenosyl-L-methionine base-pairs with uracil for all tRNA methylations. These methylations may be required during transcription of a tRNA molecule in order to limit the number of possible conformers that can occur before the molecule develops further. Fragments of tRNA were suitable substrates for enzymatic methylation; however, a subtle treatment such as UV irradiation destroyed the ability of intact tRNA to act as a substrate. It is believed that the tRNA fragments necessarily have little secondary or tertiary structure, which allows the base uracil of tRNA to pair with the adenine portion of S-adenosyl-L-methionine. This theory of the function for methyl groups is discussed in light of the properties of hypomethylated tRNA's. (39 refs)

78-6622 The Role of Specific Nucleic Acid Reactions and Their Repair. (Eng) Brookes, P. (Inst. Cancer Res., Pollards Wood Res. Station, Chalfont St. Giles, Bucks HP8 4SP, England); King, H. W.; Newbold, R.; Osborne, M. R. In: *Characterization and Treatment of Human Tumours. Proceedings of the Seventh International Symposium on the Biological Characterization of Human Tumours held in Budapest, April 13-15, 1977*. Davis, W.; Harrap, K.

R., eds. (Amsterdam: Excerpta Medica): Advances in Tumour Prevention, Detection and Characterization. Vol. 4, 332 pp.; 58-62; 1977.

The mechanisms by which methylating agents and polycyclic hydrocarbons react with DNA are reviewed. Some methylating agents (ie, N-methyl-N-nitrosourea) react with deoxyguanosine to form O⁶-methyldeoxyguanosine. It was suggested that the O⁶-methylguanine moieties in DNA would base-pair with thymine and lead to transition mutations. The extent of tumor formation due to N-methyl-N'-nitro-N-nitrosoguanidine correlates with the extent of O⁶-methylation of guanine. In addition, tissues able to excise O⁶-methylguanine from their DNA have lower tumor incidences following treatment with a carcinogen than tissues that cannot perform this function. According to studies of polycyclic hydrocarbons, an epoxide metabolite of benzo(a)pyrene (BP) and one of 7,12-dimethylbenz(a)anthracene reacts with the 2-amino group of guanine. It is not known why hydrocarbon derivatives react with amino groups that are never attacked by classical alkylating agents. Experiments with the diol epoxide and K-region epoxide of BP indicated that the diol epoxide was the more potent mutagen of the two and that it was able to induce a high frequency of mutations at nontoxic dose levels. The two examples considered suggest that cellular DNA-repair mechanisms may ultimately determine the biological consequences of DNA-carcinogen reactions. (23 refs)

78-6623 Biochemical Aspects of Chemical Carcinogenesis. (Eng) Gielen, J. E. (Laboratoire de Chimie Medicale et de Toxicologie, Institut de Pathologie, Universite De Liege, B4000 Sart Tilman par Liege 1, Belgium). *Bull Cancer (Paris)* 65(3): 249-254; 1978.

A brief review is presented of the carcinogenic abilities of polycyclic aromatic hydrocarbons (PAH), with particular reference to the enzymatic systems necessary to metabolize these carcinogens, the nature of the reactive metabolites, and the cellular targets of the active compounds. PAH are highly lipophilic, and must be made more polar (hydrosoluble) in order to be eliminated from the body. Numerous enzymes and enzyme systems such as the cytochrome P450 monooxygenases, epoxide hydratase, and glutathione-S-transferase have the ability not only to detoxify and eliminate these compounds but also to act as activating agents for them when the reaction product is more active than the parent compound. The activated compounds of PAH are epoxides and dihydrodiol epoxides, which are susceptible to reaction with cellular macromolecules. The relative basal activities (influenced by physiological parameters) of these enzymes determines the intracellular concentration of the carcinogens and are more important therefore than the absolute activity, which can be modified by administration of various chemicals. The compound most likely to be the ultimate carcinogen following benzo(a)pyrene exposure is 7,8-dihydrodiol-9,10-epoxide benzo(a)pyrene. For other unsubstituted PAH, electrophilic benzylic carbonium ions should most easily appear when

located in the so-called bay region of the molecule. Because permanent alteration of the cell results from the action of these carcinogens, it is postulated that nucleophilic centers of macromolecules are subject to electrophilic attack by these compounds. Although complexes between nucleosides and 7,8-dihydrodiol-9,10-epoxide benzo(a)pyrene have been demonstrated in vitro, this phenomenon has not yet been seen in vivo. (45 refs)

78-6624 Characteristics of Excision Repair after High Doses of UV and Chemicals to Human Cells. (Meeting Abstract). (Eng) Setlow, R. B. (Biology Department, Brookhaven Natl. Lab., Upton, NY, 11973). *Can J Genet Cytol* 20(3): 436; 1978. (4 refs)

78-6625 The Importance of the Formation and Persistence of Alkylated Bases in DNA in the Carcinogenicity of N-Nitroso Compounds (Meeting Abstract). (Eng) Pegg, A. E. (Dept. Physiology, Pennsylvania State Univ. Medical Sch., Hershey, PA, 17033). *Can J Genet Cytol* 20(3): 435-436; 1978. (3 refs)

78-6626 Two-Stage (Initiation-Promotion) Carcinogenesis In Vivo and In Vitro. (Eng) Chouroulin, I. (Institut de Recherches Scientifiques sur le Cancer, C.N.R.S., BP8, F 94800, Villejuif, France); Lasne, C. *Cancer (Paris)* 65(3): 255-264; 1978.

Current progress in the in vitro and in vivo investigation of two-stage carcinogenesis is reviewed. In vivo initiation and promotion is each an incomplete carcinogenic action; nevertheless almost all initiators are carcinogens. The promoter, on the other hand, must be irritants capable of inducing hyperplasia. Because the initiation stimulus is transmitted from cell to cell over time, it must involve cellular genetic mechanisms. Promotion, which is reversible, seems to be related to stimulation of mitosis and protein synthesis. For tumor yield should be quantitatively related to the initiator dose, while promoter effectiveness should dictate the speed of tumor development. Whereas these phenomena have been successfully demonstrated using mouse skin, difficulties have been encountered in other systems. A successful in vivo demonstration using rat fibroblasts is reported. Initiators tested were 7,12-dimethylbenz(a)anthracene (DMBA) (1 µg/ml of medium for 24 hr), benzo(a)pyrene (BaP) (1 µg/ml of medium for 6 hr), and benzo(e)pyrene (BeP) (1 µg/ml of medium for 6 hr). Promoters included 12-O-tetradecanoyl-phorbol-13-acetate (TPA) (0.1 µg/ml of medium at each passage) and croton-oil (CrO) (0.01 µg/ml of medium at each passage). Transformation criteria included acceleration of transformation of 20% of cells (by which criterion BaP and BeP followed by CrO were most effective) and acceleration to mutation in injected animals (by which criterion DM

followed by TPA was effective and BaP followed by CrO (most effective). BeP followed by CrO did not enhance carcinogenesis. These results demonstrate effective two-stage carcinogenesis in vitro, and have implications for the occurrence of human lung cancer, where an initiation-promotion model can be hypothesized. 78-6627 **Benzene--Attempts to Establish a Lower Exposure Standard in the United States. A Review.** (Eng) Zenz, C. (2418 Root River Parkway, West Allis, WI, 53227). *Scand J Work Environ Health* 4(2): 103-113; 1978.

The cause-and-effect relationship between benzene exposure and blood abnormalities, including certain leukemias, is reviewed. The National Institute for Occupational Safety and Health has recommended that occupational exposure to benzene be controlled to < 1 ppm in air. The current standard is 10 ppm. (57 refs)

78-6628 **Nitrosamines in the Atmosphere.** (Ger) Lohs, K. (Sitzungsberichte der Akademie der Wissenschaften der DDR, Berlin, E. Germany); Rolle, W.; Gehlert, H. *Akademie der Wissenschaften* (2): 99-105; 1978.

The formation, toxicity, and volatility of dialkyl nitrosamines (DAN) are reviewed. A recent study of the effect of dimethylnitrosamine in rats led to the conclusion that the formation of O-6-methylguanine is more closely associated with the carcinogenic activity of DAN than alkylation of the N-7 of guanine, as was previously thought. Nitrosamine analysis has become much more precise since the development of the thermogravimetric analyzer. Recent work has shown that diethylnitrosamine and diethylammonium nitrate can be rapidly formed in the gas phase, from NO₂ and diethylamine, without the influence of UV light. Review of the literature indicates that at 10⁻⁸ mole of nitrosamine/m³ of inspired air is dangerous to humans and also that industrial sources are releasing amounts of DAN that could quickly lead to dangerous levels. (2 refs)

78-6629 **Mycotoxins.** (Rus) Kravchenko, L. V. (Lab. Enzymology, Inst. Nutrition, Moscow, USSR); Matel'ian, V. A. *Zh Vses Khim O-Va D.I. Mendeleeva* 23(4): 400-405; 1978.

A review is presented summarizing literature pertaining to the physico-chemical properties, toxicity, and carcinogenic activity of a series of most common mycotoxins. Such mycotoxins as aflatoxins, sterigmatocystin, patulin, penicillic acid, ochratoxin, and some metabolites of Alternaria have very strong carcinogenic activity. (198 refs)

78-6630 **Oncogenesis and Vitamin A.** (Rus) Pletsityi, K. D. (Lab. Nonspecific Resistance Organism Immunity, Inst. General Pathology, Pathological Physiology, Moscow, USSR). *Vopr Onkol* 24(10): 85-92; 1978.

A review is presented of the literature concerning the role of vitamin A in tumor resistance. Experimental and clinical data has proved the association between the vitamin A deficiency and the incidence of malignant tumors. Vitamin A deficiency was shown to enhance the carcinogenic effect of benzo(a)pyrene, while administration of vitamin A or its derivatives inhibited the growth of carcinogen-induced tumors. (72 refs)

78-6631 **Inorganic Carcinogens.** (Eng) Rawson, R. W. (Univ. Texas System Cancer Center, Houston, TX). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1893-1906; 1978.

The role of trace metals such as As, Cd, Cr, Ni, Pb, and Be, most of which are nonessential, and asbestos in the genesis and growth of various cancers is reviewed. There is evidence that the presence of an excess amount of certain nonessential elements in an organ or in the whole organism may promote the development of cancers of the lung, gastrointestinal tract, and skin. (66 refs)

78-6632 **Nasopharyngeal Carcinoma.** (Eng) Andersson-Anvret, M. (Dept. Tumor Biology, Karolinska Inst., Stockholm, Sweden); Forsby, N.; Klein, G. *Prog Exp Tumor Res* 21: 100-116; 1978.

The association between Epstein-Barr virus (EBV) and nasopharyngeal carcinoma (NPC) is reviewed. Epidemiological studies suggest that there are intrinsic, probably genetic, cofactors in the etiology of NPC. At least four antigens, or complexes of antigens, have been shown to be EBV-determined: viral capsid antigen (VCA), membrane antigen (MA), early antigens (EA), and complement-fixing soluble antigen (CF/S) and nuclear antigen (EBNA), which are probably identical. Patients with NPC have high antibody titers against VCA, MA, EA (both restricted and diffuse components), and CF/S. EBNA has been found in the epithelial cells of NPC tumors, and there is a complete correlation between the expression of EBNA and detection of EBV DNA in the cells. A comparison of the antibody reactivities indicates that anti-VCA titers are relatively stable over a lifetime, but anti-EA is the most disease-related antibody. It is usually only present in patients with an acute lymphoproliferative, EBV-induced disease. NPC patients have increased IgA antibody levels; however, the EBV-specific IgA antibodies to

VCA and the diffuse component of EA decline to nondetectable levels after treatment of the tumor. The EBV DNA found in NPC tumors is present in the epithelial cells. EBV DNA is only found in the undifferentiated form of the tumor. Different strains of EBV may exist in tumors from different geographical areas. (94 refs)

- 78-6633 **Carcinogenic Mode of Action of Tissue-embedded Foreign Particles.** (Ger) Brand, G. (Dept. Microbiology, Univ. Minnesota Medical Sch., Mayo Box 196, Minneapolis, MN, 55455). *Zentralbl Bakteriol (Orig B)* 166(2/3): 159-168; 1978.

Foreign bodies such as asbestos fibers, schistosoma eggs, or artificial implants are known to cause cancer. Studies of foreign body tumorigenesis in mice have revealed a specific sequence of preneoplastic events: (1) loss of macrophage phagocytic activity; (2) fibrous conversion of the foreign bodies; and (3) during the fifth to sixth month following implantation, contact between the preneoplastic cells and the foreign body surface. The size, shape, and surface properties of the foreign bodies (chemically inert glass or plastic films) were also of decisive importance to the neoplastic process. Specific antigens and indications of immunologic surveillance were not detected. These findings may facilitate the understanding not only of asbestos carcinogenesis and the cocarcinogenic role of smoking, but of the cancer phenomenon in general. (36 refs)

- 78-6634 **Occupational Lung Disease.** (Eng) Jones, R. N. (Tulane Medical Center, New Orleans, LA); Weill, H. *Respiratory Care* 23(10): 989-998; 1978.

Occupational lung disorders are reviewed with regard to their causative agents and the pathologic responses evoked. Dust macules (which are caused by inhaling tin, barium, iron, or coal salts), pulmonary fibrosis, hypersensitivity pneumonia, beryllium lung disease, and obstructive airway diseases are discussed. Asbestos, arsenic, chromates, nickel, radioactive inhalants, the halo bischloromethyl ether, chloromethyl methyl ether, and vinyl chloride monomer may induce respiratory tract tumors. Asbestos may also cause cancer of the larynx and carcinoma of the gastrointestinal tract, and brain tumors and hemangiosarcoma of the liver may result from exposure to vinyl chloride. The diagnosis of occupational lung disease is discussed, as is the setting and enforcement of permissible dust exposure levels. (10 refs)

- 78-6635 **Cancerogenesis, Teratogenesis, Mutagenesis: Correlation Between Animal Experiments and Clinical Findings.** (Ger.) Froberg, H. (Institut für Toxikologie, E. Merck, Frankfurter Strasse 250, 6100 Darmstadt 1, W. Germany). *Arzneim Forsch* 28(11a): 1984-2001; 1978.

Carcinogenicity data from animal tests, epidemiological studies and clinical experience with humans, and mutagenicity tests are reviewed. A good correlation among in vivo carcinogenicity test results, teratogenic effects, and mutagenic effects has been found for alkylating compounds and for compounds that can be metabolized into electrophilic agents. To develop a quick test for carcinogenicity, the mutagenic effects of carcinogens on several bacteria and yeasts have been studied. *Salmonella typhimurium* (Ames test) is considered the most suitable organism for such a quick test. The false-negative rate ranges from 7%-25%. The highest false-negative rate came from a study in which many carcinogenic compounds were tested. In this study, several metals that were not carcinogenic in animals, MoVI, PtII, RhI, and RuII, gave positive results. Thus, the Ames test as currently performed is not suitable for testing the carcinogenicity of metals. With microsomal activation, the Ames test gave a 9% error rate when tested on known N-nitrosamines; for polycyclic aromatic hydrocarbons, the error rate was only 2%. Ames and coworkers have assumed that there is a quantitative relationship between mutagenicity and carcinogenicity, but other workers have not confirmed this relationship. It appears that only substances that can be converted to reactive electrophilic compounds show a positive correlation between mutagenicity and carcinogenicity. Possible reasons for a lack of correlation with other compounds include extreme volatility, lack of activating substances, and rapid reaction of the compound with metabolites present in *S. typhimurium*. (11 refs)

- 78-6636 **Structural Prognostication of Carcinogenicity and Tumor-Enhancing Activity in Various Organic Chemicals.** (Eng) Van Duuren, B. L. (Lab. Organic Chemistry, New York Univ. Medical Center, New York, NY 10016). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2 (part 1), 2404 pp.; 2071-2084; 1978.

Structure-activity relationships of direct-acting alkylating agents, tumor promoters, and cocarcinogens are reviewed. Among the 100 alkylating agents examined were epoxides (mono-, bi- and polyfunctional), β - and γ -lactones, and a variety of chloro ethers. The β -lactones are carcinogenic but the γ -lactones are not. The bifunctional epoxides exhibit carcinogenicity more frequently than the monofunctional analogs. In monofunctional agents, the presence of a reactive adjacent functional group results in carcinogenic activity. Trichloroethylene (TCE) and vinyl chloride (VC) may be metabolized via an epoxide intermediate. TCE is carcinogenic in mice but not in rats, and VC is a known human carcinogen. Because of the wide differences in chemical structure, reactivity, and physical properties of tumor promoters, cocarcinogens, and tumor inhibitors, they probably exert their a-

ities in several different ways. They may simply alter the rate of absorption and disappearance of a carcinogen, or they may alter its metabolic pathway. Tumor-promoting agents, particularly the phorbol esters, are likely to interact at the cell membrane. As a result of structure-activity studies, it has become possible to assign biological activity to certain classes of compounds that have not yet been tested. (41 refs)

- 78-6637 **Nutritional Modulation of Carcinogenesis.** (Eng) Newberne, P. M. (Dept. Nutrition Food Science, Massachusetts Inst. Technology, Cambridge, MA); Rogers, A. E.; Gross, R. L. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer in New York, NY: Vol. 1(part 1): 1193 pp.; 665-691; 1977.

Based on epidemiologic studies that clearly reveal a change in the incidence of some forms of cancer when populations move from one geographic location to another and change in habits, evidence has accumulated to indicate that nutrition is associated with resistance or susceptibility to cancer. The following positive correlations between cancer in five major target organs and environmental risk factors have been conclusively established: (1) esophagus: heavy consumption of cigarettes and alcohol; wheat bread and tea consumption; (2) stomach: low socioeconomic status; consumption of salt-smoked, or fermented foods; decreased consumption of vegetables; (3) colon: increased consumption of meats, saturated fats, and highly refined carbohydrates with low dietary fiber and decreased vitamin A; (4) liver: decreased dietary lipotropes and increased dietary fat; consumption of toxic substances such as alcohol and mycotoxins and modified microsomal enzymes; (5) breast: higher socioeconomic status, with increased consumption of animal fat; obesity, or, more likely, both increased weight and height; potential increases in estrogen synthesis. It is hoped that through continued study, nutrition may soon be used as a major modifier in efforts toward prevention of cancer. (76 refs)

- 78-6638 **Dietary Effects on Chemical Carcinogenesis in the Livers of Rats.** (Eng) Rogers, A. E. (Lab. Experimental Pathology, Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139). *Rat Hepatic Neoplasia: Workshop on Rat Liver Neoplasia* edited by William F. Merrell, Co. in *Woods Hole, October, 1974*. William F. Merrell, Co. (Woods Hole, MA): 288 pp.; 1978. 225-265; 1978.

The effects of different types of diets and of specific nutrients and additives on the development of chemically induced hepatic tumors in rats are reviewed. Natural-ingredient diets provide some degree of protection against hepatic carcinogenesis, although the mechanism by which they do so is not known.

Lipotropic factors (choline, methionine, folic acid), with the possible exception of vitamin B₁₂, protect rats against the induction of hepatic tumors by a number of chemicals, and there is evidence of direct biochemical interaction between lipotropes and carcinogens. Vitamin A protects against the induction of gastrointestinal neoplasia by aflatoxin B₁ and other carcinogens, but it does not consistently affect the induction of hepatic tumors by aflatoxin. Dietary effects on the toxicity of carcinogens may or may not correlate with their effects on carcinogenicity. Dietary manipulation offers a valuable tool for exploring the mechanisms of action of chemical carcinogens. (no refs)

- 78-6640 **The Thyroid, Prolactin, and Breast Cancer.** (Eng) VanderLaan, W. P. (Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA, 92037); Larson, B. A. *Arch Intern Med* 138(11): 1611-1612; 1978.

The role of thyroid dysfunction and prolactin secretion in the etiology of breast cancer is reviewed. Breast cancer growth in rats can be stimulated by iodine deprivation, and rat mammary gland dysplasia may be induced by thyroid-stimulating hormone (TSH) acting directly on the breast. Prolactin is influential in murine mammary tumorigenesis. In breast cancer patients, the findings of altered TSH and prolactin responses to thyrotropin-releasing hormone may be part of a general pituitary dysfunction in breast cancer. (10 refs)

- 78-6641 **Correcting a Bias?** (Eng) Hutchison, G. B. (Harvard Univ. Sch. Public Health, Boston, MA, 02115); Rothman, K. J. *N Engl J Med* 299(20): 1129-1130; 1978.

An attempt to compensate for the presumed greater detection of endometrial cancer among estrogen users by choosing as a comparison group women with benign gynecologic conditions only adds to the accumulating evidence that exogenous estrogens induce endometrial cancer. In other words, it too introduces a selection bias. (4 refs)

- 78-6642 **Menopausal Estrogens and Endometrial Cancer.** (Eng) Weiss, N. S. (Dept. Epidemiology, Univ. Washington and Fred Hutchinson Cancer Res. Center, Seattle, WA, 98195). In: *Estrogens and Cancer. Proceedings*

of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977. Colorado Regional Cancer Center (Denver, CO): 197 pp.; 27-34; 1978.

The relationship between endometrial cancer and the menopausal use of estrogens is discussed. The incidence of endometrial cancer in the United States rose sharply soon after the rapid increase in estrogen use among American menopausal women, whereas the incidence rate in England, where noncontraceptive estrogen use has been much less common, is lower than in the United States and has not increased during the same period. Five recent studies have shown that menopausal women with endometrial cancer had a greater exposure to exogenous estrogens than did controls. The incidence in users was estimated to be 3-10 times that in nonusers. Estrogen use has also been found to predispose to endometrial hyperplasia; women with this condition have an increased risk of carcinoma. Other evidence suggesting a causative role for the menopausal use of estrogens includes: (a) conditions in which endogenous estrogen levels are elevated or are not countered by progesterone secretion that predispose to endometrial cancer, (b) the use of noncontraceptive estrogens in the treatment of gonadal agenesis and breast cancer that leads to an increased incidence of endometrial cancer, and (c) endometrial proliferation as a prominent effect of estrogenic hormones. Other evidence suggests that if low-dose, short-duration estrogen therapy is used, the increased risk of endometrial cancer will be less than the average increase found in most of the recent studies. It is suggested that case control and cohort studies should be employed together in future studies of the relationship between noncontraceptive estrogen use and the development of endometrial cancer. (34 refs)

78-6643 Hormonal Carcinogenesis: A Novel Hypothesis for the Role of Hormones. (Eng) Nandi, S. (Dept. Zoology, Univ. California, Berkeley, CA, 94720). *J Environ Pathol Toxicol* 2(1): 13-20; 1978.

Information related to the role of hormones in carcinogenesis is reviewed as background for a hypothesis on hormonal carcinogenesis. The hypothesis is based on the following findings: (1) hormones regulate cell division in normal cells; (2) successful neoplastic transformation requires hormonal stimulation of cells receiving a carcinogenic insult; and (3) normal cells, when present in a high ratio, inhibit the growth of neoplastic cells. According to the hypothesis, hormones are neither mutagenic nor carcinogenic. They play a dual role in carcinogenesis induced by direct-acting carcinogens, such as viruses, chemicals, and radiation. This dual role is postulated to be (1) the fixation of neoplastically transformed cells, and (2) control of the latent period for the appearance of overt tumors by regulating the growth and ultimate death of normal cells. This would alter the ratio of normal to neoplastic cells in favor of the neoplastic cells, which would, in turn, facilitate the growth of tumor cells. This hypothesis is testable in the mammary tumor system. (40 refs)

78-6644 Use of Hormones and Human Tumorigenesis. (Eng) Lewison, E. F. (Johns Hopkins Hospital, Baltimore, MD). In: *Third International Symposium on Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer, New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 609-616; 1977.

The relationship between the long-term use of exogenous hormones and the development of malignant and benign tumors of the breast, endometrium, vagina, and liver is reviewed. Studies showing that estrogens act directly on normal breast tissue cells by promoting growth and differentiation and that there is a high level of positive estrogen receptor in the cytoplasm of about one-third of all breast cancer patients suggest that estrogen is involved in the etiology of this disease. A significant fact is that >99% of the patients are female. However, epidemiologic studies of the relationship between breast cancer and estrogens or oral contraceptives have yielded inconclusive results. Recent studies have shown conclusively that the prolonged use of estrogens by postmenopausal women is correlated with a marked increase in the risk of developing endometrial cancer. Cancer of the vagina, a relatively rare disease, has been linked to the ingestion during pregnancy of nonsteroid estrogens, including diethylstilbestrol and its various analogs, by the mothers of the patients. Primary liver tumors, liver adenomas, and liver hyperplasia have all been shown to develop with increased incidence in young women taking oral contraceptives. In determining the ultimate risk of developing malignancies in all of these situations, one must take into account the exact type of synthetic estrogen used as well as the duration of use. (24 refs)

78-6645 Pathologic Aspects of Tumors and Tumor-like Lesions in Women Taking Oral Contraceptives and Hormones. (Eng) Fechner, R. E. (Dept. Pathology, Univ. Virginia Sch. Medicine, Charlottesville, VA, 22903). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977*. Colorado Regional Cancer Center (Denver, CO): 197 pp.; 111-145; 1978.

The pathology of liver, breast, and genital tract tumors and other related lesions in women taking oral contraceptives is reviewed. In addition, studies on the incidences of these tumors are reviewed. The largest group of tumors that appear to be associated with hormones is in the liver. Liver cancer, adenoma is composed of hepatocytes lined by Kupffer cells and with nuclear variation more diverse than that seen in normal liver; it contains no bile ducts or ductules. Bile ducts do occur in focal nodular hyperplasia, and this feature is the crucial diagnostic difference between the two conditions. Gross and microscopic features of these conditions do not differ in hormone users from those in nonusers. However, some evidence suggests that there may be a quantitative increase in tumor vascular changes in women taking oral contraceptives.

ceptives, as compared with those in women not taking hormones. Hepatocellular carcinoma is also discussed. Most investigators are inclined to agree that oral contraceptives could not be incriminated in the pathogenesis of cervical dysplasia on the basis of the evidence thus far available. The endometrium is the uterine tissue most frequently altered morphologically by oral contraceptives. The changes are due mainly to progestin, which may produce a conspicuous decidual reaction, while the glands become atrophic (glandular-stromal dissociation). Endometrial adenocarcinoma has been illustrated in an endometrium that exhibited stromal-glandular dissociation. The histologic appearance of endometrial carcinomas has been unusual in two respects. One study demonstrated an excess of secretory and clear-cell carcinoma in hormone users when compared with young women with endometrial cancer who had never used oral contraceptives. The second alteration is the greater degree of eosinophilia in the neoplastic cells of women who have received hormones. Only a small proportion of uteri removed during therapy after oral contraceptive therapy demonstrate morphologic changes in the myometrium or the myomas harbored therein. Cervical adenosis has become clinically detectable during oral contraceptive therapy and has regressed when the hormones are discontinued. Breast tissue undergoes no histologically distinctive changes during contraceptive hormone therapy. However, the hormones occasionally produce lobular hyperplasia with secretory activity either in normal breast or within adenomas. (184 refs)

78-6646 **Oral Contraceptives and Cancer.** (Eng) Kretzschmar, R. M. (Dept. Obstetrics and Gynecology, Univ. Iowa, Iowa City, IA, 52240). *CA* 28(2): 8-123; 1978.

There is no convincing evidence that oral contraceptives cause cancer, but they have been associated with the occurrence of benign liver tumors. (no refs)

78-6647 **Postmenopausal Estrogens and Endometrial Cancer: A Pathologist's Overview.** (Eng) Sommers, S. C. (Dept. Pathology, Lenox Hill Hosp., New York, NY, 10021). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 43-53; 1978.

The relationship between the use of postmenopausal estrogens and the development of endometrial cancer is discussed. Previous epidemiologic-statistical and retrospective case control studies were poorly planned and failed to answer the questions of how often and how significantly perimenopausal estrogen administration may contribute to the development of endometrial carcinoma. Prospective cohort studies are

needed to avoid the acknowledged defects of case control and retrospective studies. It is suggested that, if there is a family history of endometrial or gastrointestinal carcinoma, obesity, diabetes, hypertension, proven endometrial hyperplasia or dysplasia, or an abnormal genotype, estrogens should probably not be given, as they might exaggerate an already abnormal situation and contribute eventually to development of endometrial carcinoma. In other women, estrogens may be prescribed without fear of endometrial carcinogenesis, provided that an initial endometrial specimen does not exhibit hyperplasia or dysplasia, that the dose is in the low (growth stimulating) rather than in the high (growth inhibiting) range, and that the estrogen is not given continuously. If estrogen is administered in a high dose, progestagen should be administered concomitantly about 1 wk in every 4. Follow-up endometrial aspiration or curette biopsies are desirable to appraise the endometrial response at intervals. (63 refs)

78-6648 **Effect of Oral Contraceptive Use on the Risk of Human Breast and Cervical Cancer.** (Eng) Stadel, B. V. (Natl. Inst. Child Health and Human Development, NIH, Bethesda, MD, 20014). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 89-102; 1978.

The epidemiology of breast and cervical cancers and the effect of oral contraceptive (OC) use on the risk of these cancers are reviewed. No overall increase in breast cancer risk for OC users has been observed in four case control studies or three cohort studies. However, only one study specifically analyzed possible interactions between OC use and previously reported breast cancer risk factors, such as age of first full-term birth and benign breast disease. This study suggests that OC use may increase breast cancer risk among certain subgroups of women and indicates the need for further study. The available data regarding the effect of OC use on the risk of cervical cancer and its precursors are confusing and inconclusive. Most of these data do not control directly for possible confounding between OC use and either age at first coitus or number of sexual partners. The use of such variables as socioeconomic status, marital status, and parity in an effort to control indirectly for possible confounding between OC use and sexual behavior may be insufficient. Separate evaluation of the effect of OC use on the risk of cervical cancer and its precursors for women with previously reported cervical cancer risk factors would be useful, since OC use might affect risk only among women exposed to a venereally transmitted carcinogen prior to OC use. Virtually all available studies of the effect of OC use on the risk of cervical cancer and its precursors have had cervical dysplasia or carcinoma in situ as their biologic endpoint. Diagnostic criteria for these lesions appear to vary widely, as do estimates of their invasive potential. The current information is insufficient to warrant the conclusion that OC use affects the risk of either breast or cervical cancer, but it does indicate a need for further studies. (34 refs)

- 78-6649 Breast Cancer and Menopausal Estrogens.** (Eng) Ross, R. (Dept. Pathology, Univ. Southern California, Sch. Medicine, Los Angeles, CA, 90033); Mack, T.; Gerkins, V.; Hill, A. In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 55-65; 1978.

Despite evidence implicating estrogens in mammary tumor development in animals, the role of exogenous menopausal estrogens in human breast cancer (BC) etiology remains unresolved. Of two case-control studies, the first revealed a large protective effect of hormones, but the second showed a two-fold increased risk of BC in hormone users. When the studies were combined and adjusted for age at diagnosis and menopause, estrogens were found to have no effect. In a recent study of 1,891 women using conjugated estrogens and followed for an av of 12 yr, the overall relative risk of BC was 1.3. However, women in this study who took at least 0.625 mg estrogen on other than a daily basis and followed by > 10 yr had a relative risk of 4.7. The methodology for a current case-control study designed to overcome the methodologic errors of previous studies is described. Drug histories of cases and controls matched by age, marital status, and social class are being obtained through personal interviews, medical record abstraction, and pharmacy records, and a detailed menstrual and reproductive history is also being taken. (33 refs)

- 78-6650 Oral Contraceptives and Liver Tumors.** (Eng) Bloustein, P. A. (Dept. Lab. Medicine, Wesley Medical Center, Wichita, KS, 67202). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 103-110; 1978.

Reported associations between oral contraceptive use and the development of focal nodular hyperplasia, liver adenoma, and hepatocellular carcinoma are reviewed, and the effects of oral contraceptives on liver metabolism and ultrastructure are summarized. Serum transaminase activity and bromosulphalein retention increased in women who took the first estrogen- and progestagen-containing oral contraceptives in 1960, but the incidence of markedly deranged liver function has decreased as the amount of steroids has been reduced. Liver dysfunction is usually transient, suggesting that the hepatocytes can adapt. The most striking ultrastructural change observed in the hepatocytes with oral contraceptive use was an increase in the amount of smooth endoplasmic reticulum. Some evidence suggests that the development of focal nodular hyperplasia might be related to contraceptive use, although this evidence is not as compelling as it is with other hepatic lesions. In general, the former lesion occurs in women in the child-bearing years, regardless of oral contraceptive use. Vascular lesions were described in focal nodular hyperplasia prior to the introduction of birth control pills and thus cannot be ascribed to the use of these agents. However, hemorrhage within a preexisting lesion of focal nodular

hyperplasia may be related to oral contraceptive use, because only since the advent of the pill have patients with this lesion presented with significant intrahepatic hemorrhage or acute hepatic rupture. Hepatocellular adenoma was an exceptionally uncommon tumor prior to the widespread use of oral contraceptives. The incidence of this lesion has increased in recent years in women taking oral contraceptives, especially those who had taken the hormone for several years. The most severe complication is rupture of the tumor with resultant hemorrhage. There is evidence suggesting that the tumor produces a biologically active substance that causes diarrhea. Liver cell carcinoma has been reported in women using oral contraceptive steroids and estrogen-like drugs, but the number of such cases in no way represents the type of increase in frequency that has been seen in adenomas. (29 refs)

- 78-6651 Treatment of Menopause.** (Eng) Morris, J. M. (Dept. Obstetrics and Gynecology, Yale Univ. Sch. Medicine, New Haven, CT, 06516). In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp. 13-26; 1978.

The risks and benefits of hormone replacement therapy during menopause are discussed. Although patients taking exogenous estrogens appear to have an increased risk of developing endometrial and breast cancer, there is evidence that the endometrial tumors induced by exogenous estrogen are of lower-grade malignancy than their nonexogenously induced counterparts. In post-menopausal women, estrogen administration can reverse a negative calcium balance, halt bone loss, and arrest vertebral deformity and loss of height. (19 refs)

- 78-6652 Vaginal and Cervical Pathology Associated with Prenatal Exposure to Diethylstilbestrol.** (Eng) Robboy, S. J. (Dept. Pathology, Massachusetts General Hosp., Boston, MA, 02114); Prat, J.; Welch, W. R. In: *Estrogens and Cancer. Proceedings of a meeting held by the Colorado Regional Cancer Center in Denver, Sept. 10, 1977.* Colorado Regional Cancer Center (Denver, CO): 197 pp.; 153-171; 1978.

Intrauterine exposure to diethylstilbestrol (DES) has been linked to clear cell adenocarcinoma of the vagina and cervical nonneoplastic abnormalities of the lower genital tract in women (vaginal adenosis, cervical ectropion, vaginal and cervical ridges) and, more recently, to anomalies of the epididymis and testis in men. The pathologic findings in DES-exposed subjects are reviewed at length. Ongoing animal studies of the mechanisms of DES are summarized, as are clinical studies of the natural history of DES-induced adenosis and the potential risks of consuming meat from DES-fed animals during pregnancy. (52 refs)

6653 **Alcohol and Cancer.** (Eng) Tuyns, A. J. (International Agency Res. Cancer, Lyons, France). *Alcohol Health Res World* 2(4): 20-31; 1978.

role of alcohol in the development of cancer, particularly cancer of the mouth, tongue, larynx, pharynx, esophagus, liver, and lung, is reviewed. Alcohol consumption has also been associated with stomach, pancreatic, and rectal cancer. In some of these cancers, the effects of drinking and smoking are usually combined in an additive or even multiplicative manner. (108 refs)

6654 **Biological Autoxidation. 1. Decontrolled Iron: An Ultimate Carcinogen and Toxicant: An Hypothesis.** (Eng) Kon, S. H. (Henry Dazian Dept. Chemistry, Mount Sinai Hosp., New York, NY, 10029). *Med Hypotheses* 4: 445-471; 1978.

accumulation of endogenous hydrolyzed iron that is out of the control of ferritin is hypothesized to act as an inorganic carcinogen. Uncontrolled ionic iron promotes autoxidation, which crosslinks biomolecules and produces destructive active oxygen. The disease can be initiated by the transient actions of metallic catalysts of oxidation, a foreign body, a metabolic insufficiency, a burst of ionizing radiation, or free radicals. These events give rise to porous residual bodies containing limited-access spaces (LAS), which remain as a permanent tissue imprint. The pores exclude ferritin and digestive and antiautoxidation enzymes but admit ionic iron, which, sheltered from ferritin, forms a decontrolled-iron package (DIP). Thus, a DIP is an accumulation of endogenous hydrolyzed iron in LAS, an open-pore space of a porous body. The DIP uses the energy of ambient pH fluctuations to erupt from the LAS, swamp the available ferritin, poison its surroundings, catalyze autoxidation, and crosslink cell components into additional LAS carriers. There is a striking resemblance between preneoplastic carcinogenesis and DIP growth and expansion. Protein denaturants and reagents, oxidation catalysts, metabolism inhibitors, and foreign bodies such as asbestos, all initiators of carcinogenesis, are also initiators of DIP growth. It is likely that carcinogenesis includes DIP growth as a preneoplastic stage. (121 refs)

6655 **Nitrites: The Newberne Report (Letter to Editor).** (Eng) Lachance, P. A. (Dept. Food Science, Rutgers State Univ. New Jersey, New Brunswick, NJ 08903). *Science* 202(4368): 576; 1978.

The results of a Food and Drug Administration-sponsored study of nitrites were misinterpreted. There was no solid evidence in that study that nitrites are carcinogens. The results do not permit assigning nitrite a proximate carcinogenic status, and it was stated that nitrite appears to be more a promoter of neoplasia than an initiator. (no refs)

78-6656 **N-Nitroso-N-ethylurea.** (Eng) IARC Working Group (Lyon, France). In: *IARC Monographs on the Evaluation of the Carcinogenic Risk of Chemicals to Man: Some N-Nitroso Compounds*. (Lyon: International Agency for Research on Cancer): 17: 191-215; 1978.

Experimental evidence on the carcinogenicity of N-nitroso-N-ethylurea (NEU) is reviewed. NEU has been used in the laboratory synthesis of diazoethane and has been studied for growth promoting activity in plants, but it has never been used commercially. The compound is carcinogenic in mice, rats, Syrian golden hamsters, rabbits, opossums, pigs, and monkeys. NEU produces benign and malignant tumors, the sites of which vary with the route of administration. Prenatal exposure induces tumors of the nervous system. Treatment of *Salmonella typhimurium*, *Escherichia coli*, and *Drosophila melanogaster* with NEU leads to mutations, and treatment of cultured human fibroblasts with the compound results in both chromatid and chromosome aberrations. Although no human case reports or epidemiological data were available for analysis, it was concluded that NEU should be regarded as if it were carcinogenic to humans. (101 refs)

78-6657 **Is Cigarette the Wrong Scapegoat?** (Swe) Carlens, E. (Lidingo, Sweden). *Lakartidningen* 75(40): 3531-3533; 1978.

Experimental and epidemiological studies indicate that tar containing benzopyrene (BP) is a relatively weak carcinogen. Therefore, such cigarette smoke components as acrolein, formaldehyde, and hydrocyanic acid, which contribute to BP carcinogenesis by destroying the mucociliary barrier of the lungs, are equally important factors in the genesis of lung tumors. (10 refs)

78-6658 **Is Pulmonary Dysfunction the Common Denominator for the Multiple Effects of Cigarette Smoking?** (Eng) Cohen, B. H. (Dept. Epidemiology, Johns Hopkins Univ. Sch. Hygiene and Public Health, Baltimore, MD, 21205). *Lancet* 2(8098): 1024-1027; 1978.

The hypothesis that impaired pulmonary function underlies the diversity, multiplicity, and putative "nonspecificity" of the effects of cigarette smoking was assessed in a brief literature review. The differences in degree as well as type of clinical expression probably derive from the basic role of pulmonary function in mediating the action of the many different constituents of the tobacco itself against the background of various environmental exposures and intrinsic host factors. Which of the specific effects become manifest in different individuals depends on the dynamic interplay of genes, environment, and chance that determines individual vulnerability. (38 refs)

- 78-6659 Organochlorine Pesticides and Liver Cancer Deaths in the United States, 1930-1972.** (Eng) Deichmann, W. B. (Res. and Teaching Center Toxicology, Coral Gables, FL, 33124); MacDonald, W. E. *Exotoxicol Environ Saf* 1(1): 89-110; 1977.

The association between the use of organochlorine pesticides, primarily chlorophenothane (DDT), aldrin, and dieldrin, in the US and liver cancer deaths between 1930 and 1972 was investigated. Intensive and prolonged occupational exposure to these pesticides has been found to result in increased accumulation of the compounds in the body fat, emaciation, hypertension, elevated serum cholesterol, impairment of neuromuscular function, carcinoma, and generalized pathologic conditions of the liver. Other studies, however, have indicated no undesirable effects or loss of working time as a result of pesticide exposure, in spite of high body burdens. The incidence of hepatic cancer has fallen from 8.8 per 100,000 in 1930 to 5.6 per 100,000 in 1972. This steady decline in total liver cancer death rates fails to support any clear-cut evidence of an increase in liver cancer deaths since the introduction of organochlorine pesticides in the US. If any of the organochlorine pesticide compounds do have carcinogenic potential, it will first be noted in persons engaged in the manufacture, formulation, and extensive use of these compounds. (51 refs)

- 78-6660 Carcinogenicity of Saccharin.** (Eng) Reuber, M. D. (Chemical Carcinogenesis Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501). *Environ Health Perspect* 25: 173-200; 1978.

Published and unpublished carcinogenicity studies of saccharin are reviewed. Saccharin is carcinogenic for the urinary bladder in rats and mice, with male rats being more susceptible than females. Rats exposed as fetuses develop neoplasms more readily than rats exposed as weanlings. The lesions in the urinary bladder go through the stages of hyperplasia, hyperplastic nodules, and carcinomas. Neoplasms of the urinary bladder in rats were not caused by stones, parasites, sodium, or impurities. There is a cocarcinogenic effect between saccharin and methylnitrosourea for the urinary bladder. Chronic renal disease appears to result from low doses of saccharin, tumors of the renal pelvis and urinary bladder from higher doses. Benign and malignant neoplasms at all sites are increased significantly in mice and rats ingesting higher doses of saccharin. These neoplasms are present in the reproductive and hematopoietic systems and, to a lesser extent, in the lungs, vascular system, and squamous epithelium. Saccharin initiates skin neoplasms when its application is followed by croton oil. Three epidemiological studies reportedly show no increase in cancer of the urinary bladder following saccharin use. However, a Canadian study found an estimated 60% increase in cancer of the urinary bladder associated with the use of artificial sweeteners in men. (60 refs)

- 78-6661 Viral and Cellular Contributions to Expression of the Transformed State.** (Eng) Pollack, R. I. (Dept. Microbiology, State Univ. New York, Stony Brook, NY, 11594). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 169-179; 1977.

A review is presented of cell growth control in culture and its relationship to the virally induced progression from normal to malignant phenotype. Although present understanding of growth control is limited by the inability to grow many normal cell types in culture, the fibroblast model (although quite complex) has been well studied. Diminished serum requirement, loss of density-dependent growth, and relaxation of the anchorage requirement for G_1 growth are important examples of the phenotypic changes induced by various oncogenic viruses; each is sufficient to trap a normal fibroblast in the G_1 phase of the cell cycle. Tumorigenicity requires a specific group of phenotypic changes induced by viral genes; this tumor syndrome has been elucidated for SV40-transformed rodent fibroblasts injected into athymic nude mice: it consists of loss of cytoarchitectural order, loss of anchorage requirement, and production of plasminogen activator (these are necessary but not sufficient causes for tumorigenicity in this system). Although it is known that expression of the SV40 A gene is necessary for expression of the tumor syndrome, future research is needed to determine which cellular molecules the A gene product interacts with to generate this syndrome. In addition, it is necessary to delineate syndromes of transformation for nonfibroblastic cells, which account for more than 90% of human tumors. More recently, keratinocytes, macrophages, arterial endothelial cells, capillary mural cells, and many hormone-dependent glandular cells have been put into culture and should aid researchers in unraveling the mechanism of expression of the transformed state. - 78-6662 Food: A Carcinogenic Hazard?** (Eng) Kroes, R. (Lab. Pathology, Natl. Inst. Public Health, P.O. Box 1, Bilthoven, Netherlands). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 659-664; 1977.

Information on the possible carcinogenic hazard of food is reviewed. Natural components of food that pose a carcinogenic threat include nitrate (in spinach, leeks, and purslane), fats, and proteins. Natural contaminants of food that are carcinogenic include aflatoxin, cycasin, safrole, sterigmatocystin, penicillic acid, patulin, luteoskyrin, cyclochlorotrine, and pyrrolizidine alkaloids. Manmade chemicals that contaminate

foods come from a wide range of sources. The food additives butter yellow, ponceaux SX, and 3R, guinea green, fuchsin, amaranth, furfurylfuramide, and dulcin are now relatively prohibited, based on recent findings that they may be carcinogenic. Contamination can occur from food packaging chemicals; ie, vinyl chloride, a proven carcinogen is now federally regulated. Various agricultural chemicals still in use and under suspicion include dibromoethane, monochloropropane, aramite, chlordecone, lindane, DDT, aldrin, dieldrin, and nitrogen fertilizers. In addition, essentially carcinogenic substances used for disinfection, with promotion, weed and insect control, and chemical synthesis reach food as a result of environmental pollution. The last source of carcinogenic contamination is from food processing: smoke curing introduces polycyclic aromatic hydrocarbons, nitrate and nitrite curing introduces nitrosamines, and processing through the use of fungi introduces mycotoxins into the diet. 78-6663 Potential Cancer Risk in the Graphic Arts and Textiles Industries. (Eng) Kay, K. (Environmental Sciences Lab.-Dept. Community Medicine, Mount Sinai Sch. Medicine, City Univ. New York, Fifth Ave. & 14th St., New York, NY, 10029). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 857-899; 1977.

Occupational environments in the graphic arts and textiles industries were investigated through survey of numerous establishments. Examination of printing and ink establishments provided information on a number of chemicals. Although the literature reports no carcinogenic effects of carbon black per se, high-boiling oils used with carbon black in inks may act as solvents for cancer-producing chemicals adsorbed on the carbon. Chlorinated hydrocarbon solvents, petroleum hydrocarbon solvents, and high volatility solvents are used widely and may contribute to carcinogenesis although convincing evidence of this is lacking. Among the polymers and solventless inks found in use were formaldehyde resins, halogenated aromatic amines, benzophenone, anthraquinone, and styrene, having chemical relatives that are proven carcinogens. Ballpoint and felt-pen inks employ pigments and dyes comparable to those used in printing inks and incorporate alkyd resins, glycols, allyl alcohol-styrene polymers, formaldehyde-urea-ketone and urea-formaldehyde resins. In the textiles industry, the following carcinogenic dyes have been reported: Direct black 38, Direct brown 95, Direct blue 6, Disperse blue 3, Vat green 1, and Basic green 4, all containing the chromophore, -N=N-. Among flame retardants widely used are tris (2,3-dibromopropyl) phosphate, and three of its isomers. Contaminants have been shown to be mutagenic for histidine-deficient strains of *Salmonella typhimurium*. Furthermore, chemical relatives of other flame retardants, namely, halogenated and organophosphorous compounds, are

known carcinogens. Finally, three fluorescent whitening agents, 3-benzyl-4-methyl-7-hydroxycoumarin, disodium 4,4'-bis-(2,4-dimethoxybenzamido)-2,2'-stilbenedisulfonate, and disodium 4,4'-bis-(4,6-dianilino-s-triazin-2-yl)amino-2,2'-stilbenedisulfonate have been shown to enhance the carcinogenic potency of germicidal UV radiation in mice. 78-6664 Proposal for Abatement of Polycyclic Aromatic Hydrocarbon Levels Through Standardization of Benzo(a)pyrene Level in the Air. (Ger) Tomingas, R. (No affiliation given); Pott, F. *Lufthyg Silikoseforsch* 10: 28-50; 1978.

In view of the carcinogenic effects of benzo(a)pyrene (BP) and other polycyclic aromatic hydrocarbons, the atmospheric BP level should be reduced to 10 nanograms/m³. However, this level should be adopted on an interim basis, because it cannot be regarded as perfectly safe. (61 refs)

78-6665 Rationale for One Double Event in Model for Radiation Carcinogenesis (Letter to Editor). (Eng) Baum, J. W. (Safety and Environmental Protection Div., Brookhaven Natl. Lab., Upton, NY, 11973). *Health Phys* 35(4): 581-582; 1978.

The author responds to criticism of an article on the development of the multiple simultaneous event model for radiation carcinogenesis in which the critics suggest that two double events should have been considered. Two double events had been considered and rejected because of poor fits to the experimental data. A rationale for the absence of two double events is provided by considering the possibility that these events are gene alterations: two genes located near each other at the end of the chromosome may both be lost due to a terminal deletion, but there may be no similar mechanism for a second double event in the same cell or its ancestors. The critics also referred to claims for the predictive power of the model. The model was used to make predictions primarily to design experiments to test it further and improve the model. Claims were not made concerning the probability that the predictions would be validated. (2 refs)

78-6666 Formation of Thymine Containing Dimers in Skin Exposed to Ultraviolet Radiation. (Eng) Johnson, B. E. (Dept. Dermatology, Univ. Dundee, Dundee, Scotland). *Bull Cancer (Paris)* 65(3): 283-297; 1978.

A review is presented of the formation of thymine dimers in skin exposed to UV radiation (UVR). UVR is known to damage nuclear DNA, causing primarily pyrimidine-pyrimidine dimers. Although thymine is always a constituent of the dimer, thymine-cytosine dimers are also readily formed. Thymine dimers revert to the monomeric form after exposure to short

wavelength UVR (240 nanometers [nm]). Photoreactivation (a photoenzymatic process dependent on long wavelength UVR [320/390 nm] or even visible radiation) also repairs dimers, although it is not well documented in mammalian systems. However, excision repair (dark repair) has been demonstrated in humans. Studies with ³H-thymidine labeling and fluorescent antibody binding have provided evidence that DNA is photochemically changed in vivo in skin exposed to UVR, and that this change in DNA involves the formation of thymine dimers. Estimates of the yield of these dimers vary with radiation dose and wavelength, but the documented range is 0.016-2.6% of total DNA activity. In vitro studies have indicated linear increases in dimer yields over the range 50-1,000 Joules (J)/meter² (m²), and an exposure of monolayer cultures to 100 J/m² at 254 or 260 nm yielded a common value of approx 0.45% of total DNA activity as dimers. The most efficient dimer-forming activity appears to occur at approx 280-290 nm, with efficiency dropping off at both limits, perhaps more steeply at the upper end. Evidence concerning the persistence of dimers in vivo is conflicting, but a decrease in dimer incidence with time after irradiation appears to occur. Although thymine-containing dimers are formed in mammalian skin exposed to UVR in vivo, a relationship between this phenomenon and neoplastic transformation in skin remains to be proven. (73 refs)

- 78-6667 **The Controversy over the Health Effects of Radiation.** (Eng) Najarian, T. (Boston Veterans Admin. Hosp., Boston, MA). *Technol Review* 81(2): 74-82; 1978.

Nuclear workers exposed to low levels of ionizing radiation at the Portsmouth Naval Shipyard [av lifetime exposures of 2-10 Rems (Roentgen equivalent man)] and the Hanford Atomic Plant (av lifetime exposures of 1-15 Rems) are developing leukemia and/or multiple myeloma and pancreatic cancer at higher than expected rates. An excess of leukemia deaths has also been reported in men exposed to 1 Rem during a Nevada atom bomb test. The new data are either faulty or low-level radiation is much more harmful than was assumed previously. (11 refs)

- 78-6668 **X-Ray Dose Fractionation and Oncogenic Transformations in Cultured Mouse Embryo Cells (2 Letters to Editor).** (Eng) Peto, R. (Dept. Regius Professor Medicine, Radcliffe Infirmary, Oxford, England); Hall, E. J.; Miller, R. *Nature* 274(5674): 926; 1978.

In a previous study of the x-ray transformation of cultured cells, an inappropriate statistical technique was used to present the data, and, as a result, the accuracy of the data in some cases was overestimated considerably. In a reply, the authors agree with this criticism but they emphasize that the conclusion that split doses produce more transformations than a single exposure of the same total dose still holds. (1 ref.)

- 78-6669 **Molecular Biological Aspects of Oncogenesis Caused by RNA Tumor Viruses.** (Ger) Chanock, P. (Abteilung fur Molekularbiologie, J.-W.-Goethe-Universität, Theodor-Stern-Kai 7, 6000 Frankfurt-Main 70, Germany); Ebener, U.; Steel, L. K.; Laube, H.; Kornhuber, B.; Thorbeck, R. R. *Klin Paediatr* 190(1): 9-27; 1978.

The molecular mechanisms by which RNA tumor viruses (oncornaviruses) transfer their genetic information from genomic RNA (70S RNA) of the virions to cellular DNA, which leads to neoplastic transformation, are discussed. Special attention is focused on the biochemical and serological properties of reverse transcriptase (RT) and the role of the enzyme in the life cycle of RNA tumor viruses. The role of RT in myelofibrosis is also discussed. This RT is antigenically related to the RT of certain primate RNA tumor viruses as to that of human leukemia cells. The role of RT inhibition in viral oncogenesis, particularly that of partially thiolated polycytidylic acid (MPC), which has a high binding affinity to viral RT, is reviewed. The results of the use of MPC in a few leukemia patients are reported. (141 refs.)

- 78-6670 **The Oncogenic Potential of Viruses.** (Eng) Irfinger, W. (Institut für Genetik, Abt. für Virologie, Universität Köln, Weyertal 121, 5000 Cologne 41, Germany). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 87-110; 1977.

The oncogenic potential of viruses is reviewed with respect to the mechanism of malignant transformation. A variety of viruses can transform cells in culture or induce tumors in animals. A transformed or tumor cell can be distinguished from a normal cell, but transformed cells do not always exhibit all the properties of tumor cells. In virus-transformed cells, viral DNA persists frequently in covalent linkage with cellular DNA. Viral DNA often is integrated in the form of fragments. In cells transformed by adenovirus type 12 and simian virus 40, the sites of integration of the viral genome appear to differ from one cell line to another. In transformed cells, specific viral functions are expressed; in the case of homologous cells transformed by RNA tumor viruses, the entire viral genome is transcribed, and infectious virus is produced. Specific viral genes appear to be essential for transformation, in that mutants lacking these genes cannot transform. However, normal cells contain and express these similar genes without being transformed. In fact, nearly all apparently normal cells carry endogenous viruses belonging to the RNA tumor virus group. Several possible mechanisms relating the integration of viral genomes to neoplastic transformation are proposed: (1) fixation of the viral genome in host cells; (2) specific viral gene products (under host control) are responsible for transformation; (3) integration of viral genes causes mutations; (4) chromosome aberrations and

nslocations; (5) repair mechanisms in eukaryotic cells; and "hit-and-run" mechanism. Each of these hypotheses is incompatible with experimental observations, although they may be too limited to explain the actual biologic phenomenon of transformation. In different systems, transformation may be caused at different levels, and different principles may be involved. (32 refs)

78-6671 Viral "Tumor Antigens": A Novel Type of Mammalian Regulator Protein. (Eng) Weil, R. (Dept. Molecular Biology, Univ. Geneva, 30 quai Ernest-Ansermet, CH-1211 Geneva 4, Switzerland). *Biochim Biophys Acta* 516(3): 301-388; 1978.

The biological relevance of polyoma virus (PyV), simian virus (SV40), and the papilloma viruses is reviewed in the general context of cell and tumor biology. The gene products of PyV and SV40, ie, their virus-specific tumor (T) antigens, seem to represent a novel type of mammalian regulator protein. There is a striking contrast between the broad spectrum of biological effects induced by SV40 and PyV and the small size of their genome. The late region of both viruses comprises two (possibly 3) genes that specify the major (VP1) and minor (VP2 and VP3) capsid proteins. The early region, expressed before onset of viral DNA replication, comprises approximately 50% of the viral genome. It contains most of the information for lytic infection and all for abortive infection, induction of mitosis, initiation and maintenance of cell transformation, tumor formation in animals, and, possibly, for the repression of virus-specific transplantation antigens. The experimental evidence is compatible with the hypothesis that the biological effects of the early region are mediated by T antigens, although their mode of action is not known. Additional topics covered include new antigens (transplantation, surface, and T antigens) in virus-induced tumors, transformation of mammalian cells in vitro, cytological and molecular events of lytic and abortive infection with PyV and SV40 in tissue culture cells, the nature and biological significance of the virus-specific imprints in PyV- and SV40-transformed cells, and virus-specific pleiotropic effector genes and their significance for cell transformation and tumor induction. (717 refs).

78-6672 Advances in the Viral Etiology of Leukemia and Lymphoma. (Eng) Gallo, R. C. (Lab. Tumor Cell Biology, NCI, Bethesda, MD, 20014); Meyskens, F. L. *Leukemia Hematol* 15(4): 379-398; 1978.

The emphasis of this review is a critical examination of evidence for the presence of RNA tumor virus information in human leukemia. This evidence comprises the detection of extracytoplasmic particles with properties of known oncornaviruses and of reverse transcriptase (RT) related to murine and certain nonhuman primate enzymes, the rare demonstration of oncornaviruses by electron microscopy, and demon-

stration of extracellular viral particles. It is not known how the viral information enters humans and if it is important for leukemia or any disease. The major difficulty in linking C-type oncornaviruses with human disease is the rarity of isolating replicating biologically active virus from human tissue. This problem is approached by reviewing conditions under which most animal isolates are obtained. Baboon endogenous virus, simian sarcoma virus (SiSV), and gibbon ape leukemia virus may be of special interest, since components related to these viruses have been reported in human leukemic tissues. However, there are also reports of (1) a transient release of virallike particles, (2) isolation of a partially characterized infectious or transforming virus, and (3) replicating infectious virus from human cells. Failure to detect SiSV-related proviral nucleic acid sequences in human leukemic tissues may be due to the facts that SiSV is integrated only in a rare cell, complete SiSV is integrated and then completely or partially excised, or infecting virus is integrated in a tissue remote from the primary phenotypic expression. Several explanations are given for the presence of intracytoplasmic particles, which have several properties similar to those of oncornaviruses, in human leukemia cells. The detection of oncornaviruslike particles, RT and specific antibody to RT on the surface of specific types of leukemic cells may lead to the development of markers for human leukemia. (103 refs)

78-6673 The Structure and Expression of Human Herpesvirus DNAs in Productive Infection and in Transformed Cells. (Eng) Roizman, B. (Committee on Virology, Univ. Chicago, Chicago, IL, 60637); Frenkel, N.; Kieff, E. D.; Spear, P. G. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conference on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1069-1111; 1977.

The structure of herpesvirus DNA and its expression during the reproductive cycle and in transformed cells are reviewed. Evidence is presented for coordinate and sequential synthesis of viral gene products, and mechanisms and requirements for this sequential synthesis are also reviewed. Several lines of evidence indicate that posttranscriptional processing of viral RNA plays a major role in the initiation of viral polypeptide synthesis. Two representatives from the β class of herpes simplex virus (HSV) proteins (thymidine kinase and VP143) and one from the γ class (a glycoprotein) are expressed in some transformed cell lines. In studies of the presence of HSV DNA and RNA in transformed cells, the entire genome was never found. The fraction of the genome retained varied from one cell line to another and in different sublines of the same line. The number of copies of the retained sequences was relatively low. Studies with Epstein-Barr virus (EBV)-infected cells indicate that the majority of reproductively infected cell lines contain most and probably all of the EBV genome. The synthesis of viral DNA in reproductively infected cells is linked to the synthesis of cell DNA. The differences between EBV and

HSV might be a consequence of differences in inherent regulation of viral gene function in HSV- and EBV-infected cells or they might be due to differences in the inherent permissiveness of the cells transformed by these viruses. Cells transformed by HSV are permissive, whereas those transformed by EBV are largely nonpermissive. Since EBV replicates only in B lymphocytes, cell factors present in the permissive host cell but lacking in the more restrictive lymphocytes could account for the difference between HSV and EBV in the retention and expression of viral genes in transformed cells. (164 refs)

- 78-6674 RD-114 Virus: Characterization and Identification.** (Eng) McAllister, R. M. (Children's Hosp. Los Angeles, 4650 Sunset Blvd., Los Angeles, CA, 90027); Gardner, M. B.; Nicolson, M. O.; Gilden, R. V.; Davidson, N. *Prog Exp Tumor Res* 21: 196-215; 1978.

Studies performed to characterize and identify RD-114 virus and to determine its role in feline and human cancer are reviewed. RD-114 virus is a xenotropic, endogenous virus of domestic cats and of several closely related feline species. A relationship between RD-114 and endogenous baboon C-type viruses has led to the suggestion that under natural conditions, C-type viral genes can be transferred between remotely phylogenically related species. Electron microscopy of the high-mol-wt RNA extracted from RD-114 virus showed that it was an inverted dimer containing two monomer subunits with symmetrically placed loops. The two monomers are joined at their nonpoly(adenosine) ends. The dimer linkage and symmetrical loops seen in RD-114 viral RNA probably are a prototype for common structural features of all mammalian C-type viral RNA's. Transfection studies indicated that human rhabdomyosarcoma productively infected with RD-114 virus contained virus-specific DNA that specifies complete information for progeny virus formation. This DNA is integrated into the chromosomal DNA. RD-114 RNA was detected in most malignant feline tissues that transcribe feline leukemia virus (FeLV) RNA, but the converse was not seen. Thus, RD-114 gene expression may be a function of dividing cells and may be activated by FeLV infection. In older cats with naturally occurring cancer, however, transcription and translation of the endogenous RD-114 genome was not detected in the absence of FeLV expression. (78 refs)

- 78-6675 Synthesis and Processing of the Translational Products of RNA Tumor Viruses.** (Eng) Jamjoom, G. A. (Riyadh Univ. Sch. Medicine, Riyadh, Saudi Arabia); Arlinghaus, R. B. *Methods Cancer Res* 15: 3-67; 1978.

The characterization of the translation products of some RNA tumor viruses is reviewed. The virus life cycle, the structure of the viral genome, and the identification and mapping of viral genes are discussed. The major polypeptides of

the mature virions of murine and avian C-type viruses are tabulated. Studies of virus-specific messenger RNA (mRNA) indicate that the mRNA's for the *gag* and *pol* gene products are genome-length RNA species that appear to be identical to the viral genomic RNA. The mRNA's for the *env* and *src* gene products include segments of the genome extending from the *env* or *src* gene, respectively, to the 3'-end. The gene product is required for cell transformation. Modified, uncleaved precursors of the core proteins have been identified on the surface of mouse leukemia cells. The ability of these precursors to interact with nucleic acids and to associate with the cell membrane suggests that they may be capable of interfering with normal processes under conditions in which they accumulate in the cells. Exchange of genetic material among endogenous viruses of the murine system may play a role in the etiology of mouse leukemia. Evidence that the recombinant MCF viruses are the cause of leukemia in AKR mice is suggestive but still circumstantial. Studies of the peptide maps of gp70 molecules from MCF viruses and AKV viruses indicate that recombination does occur and that it occurs in the *env* gene. There is probably more than one way in which cells can become malignant, at least where C-type viruses are concerned. Two different genes, *src* and *env*, appear to be important in virus-induced sarcomas and leukemias, respectively. The gene products are different in structure, and their mode of action may also be different. (242 refs)

- 78-6676 Avian Leukemia Viruses: Interaction with Target Cells In Vivo and In Vitro.** (Eng) G. T. (German Cancer Res. Center, Neuenheimerfeld 2, D-6900 Heidelberg, W. Germany); Beug, H. *Biochim Biophys Acta* 516(3): 269-299; 1978.

The origin, oncogenic spectrum, in vitro target cell specificity, and genetic properties of avian leukemia viruses (ALV) are reviewed. Both nondefective LV, which predominantly induce lymphatic leukemias after long latency periods, and defective LV, which predominantly cause acute erythroid and myeloid leukemias after short latency periods, are considered. Susceptibility and resistance to avian sarcoma virus (ASV) and nondefective LV are determined by dominant cellular genes and by specific properties of the lymphoid target cells. Nongenetic factors that determine susceptibility and resistance include the host immune system, inoculation route, the way in which the virus was passaged or selected, and the type of tumor cells from which the virus was obtained. The oncogenic spectrum and latency period do not allow an accurate distinction between ASV and the different types of ALV. Since none of the ALV apparently possess the *src* gene, ASV, this property is proposed as a main distinguishing criterion. It is suggested that highly leukemogenic, defective LV have evolved from low leukemogenic, nondefective strains in a multistep process involving the acquisition of several properties. A tentative and highly speculative model of leukemogenesis by defective LV is presented. The model is based on three assumptions: the transformation gene of defective LV represents a modified sequence of a cellular gene.

red for normal differentiation; a necessary step in topopoietic differentiation is the interaction of an early differentiation factor with a certain cellular protein, thereby triggering the synthesis or activation of differentiation factors characteristic of later stages; the virus-coded transformation is still capable of binding to the early differentiation factor. The most obvious explanation for the transformation of cell specificity of ALV in hematopoietic cells is the ability that they are able to infect and replicate only in certain types of cells. (150 refs)

77 Oncornavirus Leukemogenesis as a Model for Selective Neoplastic Transformation. (Eng) Gardner, I. L. (Lab. Experimental Oncology, Dept. Pathology, Stanford Univ., Stanford, CA, 94305); Baird, S. In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 135-152; 1977.

Review is presented of the classification, pathogenetic role, and functions of oncornaviruses (ORV). ORV are subdivided into two groups on the basis of whether they carry the early or late gene for the expression of the malignant phenotype in target cells. Specific loci on the chromosomes of rapidly transforming (RT) ORV code for malignant phenotype expression within hours to days after host cells are infected. The genome of the RT avian ORV has been defined by the coding genes: *gag* which codes for a polyprotein precursor; *pol* which codes for nucleic acid polymerases; *env* which codes for a budding site polyprotein; *sarc*, the transforming gene which codes for common oligonucleotides; and *poly* whose function is unknown. Most RT ORV are replication-defective and require the aid of a "helper virus" to produce bud-derivations in host cells. Some ORV are slowly transforming and induce lymphocytic-leukemia weeks to months after infection into target host cells; helper viruses usually fall into this group. These viruses do not carry the *sarc* gene and are not able to transform lymphocytes but may transform fibroblasts. Many model systems emphasize the fact that malignant transformation by ST ORV requires a specific interaction between cell and virus and that replication and transcription of the viral genome is not sufficient to cause malignant transformation in cells other than susceptible thymic lymphocytes. Pathogenesis by ST ORV involves preleukemic and leukemic phases that select for expression of virion proto-oncogenes. Various models are presented that attempt to account for the origin, embryonic function, and leukemogenesis of these viruses including the oncogene, provirus, enhancer, and receptor-mediated transformation models. (24

Central Veterinary Inst., Lelystad, Netherlands); Bloemers, H. P. *Biochim Biophys Acta* 516(3): 249-268; 1978.

Recent developments concerning the genetic functions of murine sarcoma viruses (SV) and other replication-defective (RD) mammalian C-type viruses [Abelson leukemia virus (AbLV), nonmurine mammalian SV, spleen focus-forming virus (SFFV)] are reviewed. These viruses share several characteristics: they are able to transform cells in vitro and are oncogenic in vivo; they are RD and can be rescued from nonproducer cells by helper LV, yielding pseudotype viruses; their genome, which consists of a 30S RNA subunit (approx 6,000 nucleotides), evolved by recombination of LV-specific genetic information and sequences derived from normal rat cells (Kirsten and Harvey SV), normal mouse cells (Moloney SV), or xenotropic murine LV (SFFV). The origin of the non-LV sequences in the genomes of AbLV, feline SV, and woolly monkey SV is unknown. At least one of the functions of the LV sequences in the RD viral genomes may be to provide 3'- and 5'-terminal ends necessary for circularization and integration of the defective genome in the chromosomal DNA of a susceptible host cell. Several findings are given to support this speculation. The gene products of the *gag*, *pol*, or *env* genes of the LV genome are apparently not required for cell transformation by SV because they are partly or completely absent in transformed nonproducer cells infected by different SV. This does not exclude the possibility that unexpressed *gag*, *pol*, or *env* gene sequences are present and play a role in transformation or that a putative LV-specific *onc* gene cooperates somehow with SV-specific sequences. The non-LV sequences in the genome of most RD viruses are not related to each other. Apparently, SV and other RD transforming C-type viruses are vehicles of sequences that are involved in malignant transformation and, possibly, in unknown processes in normal cells. (145 refs)

78-6679 Search for RNA Tumor Virus in Humans. (Eng) Gardner, M. B. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90033); Rashed, S.; Shimizu, S.; Rongey, R. W.; Henderson, B. E.; McAllister, R. M.; Klement, V.; Charman, H. P.; Gilden, R. V.; Heberling, R. L.; Huebner, R. J. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation.* Hiatt, H. H.; Watson, J. D.; Winston, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory: Origins of Human Cancer. Vol. 4 (Book B), 699 pp.; 1235-1251; 1977.

A number of unsuccessful attempts to identify RNA tumor viruses in human material, using techniques that have proved successful in identifying RNA tumor viruses in animal tumor systems, are summarized. Virus particles could not be identified by electron microscopy, infectious viruses could not be isolated from cultured human tissues, and virus antigens or antibodies could not be identified by radioimmunoassay in a large number of human specimens. These specimens were tissues and sera from patients with a variety of cancers and

78-6680 The Genome of the Mammalian Sarcoma Viruses. (Eng) Van Zaane, D. (Dept. Virology,

diseases (sarcomas, carcinomas, lymphomas, leukemias, lupus erythematosus, xeroderma pigmentosum, and others). The fact that no antibodies to the well-characterized RNA tumor viruses of animal origin were detected in the many hundreds of human sera tested (not even in sera from individuals known to have been exposed to such viruses, eg, feline leukemia virus) is strong evidence against the horizontal infection of humans with any of the known mammalian C-type viruses. These results, however, do not rule out the possibility that noninfectious endogenous RNA tumor viral genomes are present in human cells. (55 refs)

- 78-6680 Limited In Vitro Replicative Lifespan of Cultured Human Epithelial Cells: A Survey of Recent Literature.** (Eng) Ruben, R. L. (Dept. Anatomy, Hahnemann Medical Coll., 230 Broad St., Philadelphia, PA, 19102). *Growth* 42(10): 357-368; 1978.

The literature concerning limits to the in vitro replicative life span of normal, neoplastic, and virus-transformed human epithelial cells is reviewed. Normal diploid cells routinely undergo protracted crisis in vitro, leading to the eventual loss of the cultures. Epithelial cell tumors, such as melanomas, oat cell carcinomas, and colorectal adenocarcinomas, have met with greater culturing success. However, all cell lines surviving long-term culture have had an aneuploid karyotype. Neoplastic and virus-transformed cells either degenerate in culture if diploid or survive the degenerative phase if aneuploid. Since most cells of autochthonous tumors in vivo are diploid, aneuploidy and immortality may be associated with primary or secondary transformation in vitro rather than with malignancy in vivo. In view of this evidence, the concept that neoplastic or virus-transformed cells possess unlimited potential for division should be reevaluated. (66 refs)

- 78-6681 Patterns of Gene Expression and the Cellular Origins of Human Leukaemias.** (Eng) Greaves, M. (Membrane Immunology Lab., Imperial Cancer Res. Fund, London, England); Janossy, G. *Biochim Biophys Acta* 516(2): 193-230; 1978.

Detailed phenotypic profiles on human lymphoid leukemias and on permanent cell lines established from the leukemic cells were studied to determine whether there are any consistent antigenic properties of these leukemias and whether there are any antigens of the tumor cells that could be recognized by the host. The currently available data suggest that: (1) most, if not all, of human hematopoietic malignancies are monoclonal derivatives of cells resident at the time of leukemia initiation in various linkage and differentiation compartments from the common lymphomyeloid progenitors; (2) with improved banding techniques, a high frequency of non-random chromosomal alterations are detectable in leukemia; (3) leukemic cells express a relatively stable morphological,

cytochemical, enzymatic, and antigenic phenotype that is probably unique for and qualitatively normal for the cell lineage in which the disease arises; and (4) there is no unequivocal evidence at present for leukemia-specific membrane antigen or other alterations. These interpretations challenge the rationale of immunotherapy aimed at deliberate autoimmunity in leukemia and suggest that consistent and qualitatively unique membrane changes in neoplasia may not exist. (22 refs)

- 78-6682 Stress and Disease: The Missing Link. A Vasoconstrictor Theory. III. Stress, Vasospasm and General Disease.** (Eng) Boyd, G. W. (Univ. Dept. Medicine, 4 Collins St., Hobart 7000, Australia). *Med Hypotheses* 4(5): 432-444; 1978.

Repeated ischemic cell damage from vasospasm may be a factor in the development of autoimmune disease and cancer. DNA may be altered directly or through errors in DNA replication. The similarities between viral transformation and neoplasia have led to the proposition that much cancer might be explained if, as a species, humans have evolved by the gradual build-up of viruses. (66 refs)

- 78-6683 Herpesviruses, Veneral Disease, and Cancer.** (Eng) Rapp, F. (Dept. Microbiology, Milton S. Eisenhower Medical Center, Pennsylvania State Univ., Hershey, PA, 17033). *Am Sci* 66(6): 670-674; 1978.

The probability is significant that certain human tumors may, in part, be caused by herpesviruses (HV). Epstein-Barr virus is uniformly associated with Burkitt's lymphoma, nasopharyngeal carcinoma in the southern Chinese, and a significant percentage of non-African lymphomas. Herpes simplex virus type 2, which causes venereal diseases, is associated with cervical cancer. All HV cause cells to synthesize DNA and undergo mitosis, and they can transform normal cells from many species to cells with malignant properties. (10 refs)

- 78-6684 Epidermodysplasia Verruciformis. An Autosomal Recessive Disease Characterized by Viral Warts and Skin Cancer. A Model for Viral Oncogenesis.** (Eng) Lutzner, M. A. (Dermatology Branch, Room 231, Building 10, NCI, NIH, Bethesda, MD, 20014). *Bull Cancer (Paris)* 65(2): 169-182; 1978.

The case reports of 147 epidermodysplasia verruciformis (EV) patients comprising 125 families were reviewed. EV is an autosomal recessive disease that usually begins in infancy or childhood, with an average age of onset of 9. It was found that EV has no racial predisposition and no geographic preference, and it occurs with the same frequency in both sexes.

warts are most common, but pityriasis-like warts occur in approx 75% of patients. The warts are disseminated and chronic. Cancer may develop as early as age 13; the average age at onset is 31. About one-third of the patients develop cancer of the skin, usually in exposed areas. The cancer is often squamous cell carcinoma. The average time from wart to cancer is 24 yr, but cancer has been developed in as little as 2 yr. Malignant transformation is usually in carcinoma-in situ of the Bowenoid type or squamous cell carcinoma. Two deaths occurred by local invasion; one metastasis was recorded. One patient died of Burkitt's lymphoma and another was reported to have disseminated reticulosis. Approx 8% of the patients are mentally retarded. Humoral immunity is normal, but cell-mediated immunity is depressed in most patients. The gene defect in this disease has not yet been uncovered. (135 refs)

685 Hepatocellular Carcinoma and the Hepatitis B Virus: Evidence for a Causal Association. (Eng) Weiss, R. A. (Lab. Epidemiology, New York Blood Center, New York, NY). *Prog Med Virol* 24: 40-69; 1978.

Evidence is presented in support of the hypothesis that hepatitis B virus (HBV) is a primary etiological agent in the development of hepatocellular carcinoma (HCC). HCC is widespread in parts of Africa and southeast Asia, but relatively uncommon in the US and other Western countries. Patients in the high-incidence areas are quite young, and they are predominantly male. The hypothesis is supported by the similarity in the geographic distribution of HCC and HBV, evidenced by radioimmunoassay of the HBV surface antigen (HBsAg). Moreover, there is an unusually high frequency of HBsAg and antibody to the hepatitis B core antigen (anti-HBc) in HCC patients; the amount of free circulating surface antigen seems to be relatively low. Based on available information, the relative risk of past HBV infection in HCC patients is 1.0-1.5 in high-incidence areas and 10-15 in low-incidence areas. HBsAg prevalence in high-incidence areas appears to be inversely related to patient age, and mother-child transmission is suspected. Although HCC is strongly associated with the HBsAg carrier state, genetic and environmental factors (eg, malaria, malnutrition) may also contribute to susceptibility to HCC. (114 refs)

686 Epigenetic and Viral Aspects of Cancer: Group Report. (Eng) Weiss, R. A. (Imperial Cancer Research Fund Labs., Lincoln's Inn Fields, P.O. Box 123, London WC2A 3PX, England); Baserga, R. L.; Basilico, C.; Bernhard, H.; Bustan, H.; Gardner, R. L.; Green, H.; Illmensee, K.; Jisch, R.; Kaplan, H.; Koprowski, H.; Lilly, F.; McGuire, E.; Pollack, R. E.; Sato, G. H.; Weissman, I. L. In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 269-288; 1977.

Epigenetic and viral hypotheses of carcinogenesis are summarized. Teratocarcinoma development usually involves transformation from a malignant pluripotent stem cell to non-malignant, differentiated progeny. This reversibility of the neoplastic state is an interesting concept for further research, especially since several human tumors of fetal origin, including retinoblastoma and Wilms' tumor, frequently regress postnatally. There is evidence that hormones play a role in tumor development, perhaps by activating an oncogene. Recent developments in culture methods are clarifying hormone requirements and interactions in neoplastic cell lines. Transformation by oncogenic DNA viruses appears to require the synthesis of specific viral gene products, with integration of the viral genome or genome fragments being essential for persistence of the transformed state. Papovaviruses, whose early genome region codes for both large T (tumor) and small t antigens, cause parotid gland tumors in animals and benign warts in humans. Most transforming RNA viruses (retroviruses) carry the oncogene *sarc*, but their replication is dependent on helper viruses that possess all virion genes. Although simian sarcoma helper virus and baboon endogenous virus have been isolated from humans, they have not been implicated in human disease. Papilloma virus, the cause of warts, is the only virus known to cause tumors in humans. (13 refs)

78-6687 Tumor Phenotype and Progression: Group Report. (Eng) Eichmann, K. P. (Institut für Immunologie und Genetik, Deutsches Krebsforschungszentrum, Im Neuenheimer Feld 280, 6900 Heidelberg, W. Germany); Askonas, B. A.; Franke, W. W.; Howard, J. C.; Lennox, E. S.; Mitchison, N. A.; Nicolson, G. L.; Ohno, S.; Rajewsky, K. In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 289-304; 1977.

Information concerning the phenotype of malignant cells and the immune reaction to malignant cells is reviewed. Topics discussed include the morphologic and biochemical properties of the tumor cell membrane, the three-dimensional arrangement of the malignant cells, characteristics of tumor cells with a high rate of metastasis, genetic characteristics of malignant cells, tumor cell antigens, and the biological function of antigens. A review of host responses to tumors includes immune surveillance, the role of immunity in metastasis, the association between the presence of histocompatibility antigens and susceptibility to tumors, manipulation of the immune system (ie, enhancement of tumor immunogenicity, stimulation of lymphocyte compartments, and idiotypic manipulation), nonspecific defense mechanisms, and tumor-associated antigens. (22 refs)

78-6688 Immune Surveillance. (Eng) Howard, J. C. (Dept. Immunology, ARC Inst. Animal Physi-

ology, Brabraham, Cambridge CB2 4AT, England). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977*. Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 227-245; 1977.

The "strong" form of the immunosurveillance theory is discussed. This theory differs from weaker versions in asserting that the "true" tumor incidence in animals endowed with an immune system is higher than the observed incidence and that the difference is accounted for by the activity of the immune system in recognizing new antigens on incipient neoplastic cells and disposing of the cells that bear them. Two statements must be true for the strong theory of immune surveillance to be valid: (1) immunodepression will lead to an increase in the incidence of tumors in any age class; and (2) incipient neoplasias will be immunogenic. The concept has not stood up to experimental test. A generalized increase in spontaneous tumor incidence is not seen in experimental or natural states of immunodepression. Even highly immunogenic tumors are no more easily induced in immunodepressed animals than in normal controls. Only virus-induced cancers show an increased incidence in immunodepressed animals, just as such animals are most susceptible to nononcogenic viral infections. There is no evidence that the incidence of overt cancer is limited by the activity of the immune system except in the case of horizontally transmitted oncogenic viruses. It is worth wondering why immune surveillance is not effective in other situations in which tumors are highly antigenic. (25 refs)

78-6689 Some New Data on the Pathogenesis of Chronic Lymphoid Leukemia (Meeting Abstract). (Rus) Polianskaia, A. M. (No affiliation given). *Vopr Onkol* 24(9): 121; 1978. (no refs)

78-6690 Mechanisms of Tumor Immunity. (Eng) Cohen, S. (Dept. Pathology, Univ. Connecticut Health Center, Farmington, CT, 06032); Cohen, M. *Am J Pathol* 93(2): 449-457; 1978.

Ways in which the immune response system is able to effect the proliferation of tumor cells are reviewed. The immune mechanisms of tumor-cell killing are divided into two groups: cell-mediated and non-cell-mediated mechanisms. Effector cells in tumor cell-mediated destruction include lymphocytes, which secrete soluble mediators, participate in antibody-dependent reactions, and can become cytotoxic themselves; macrophages, which may be rendered cytotoxic by an arming factor from activated T lymphocytes; and granulocytes, which participate in antibody-dependent cytotoxic reactions. Noncellular mechanisms of tumor-cell destruction include lymphotoxins, produced by lymphocytes stimulated with specific antigen or with nonspecific mitogens that can kill or damage various cell lines in vitro; and complement, which

can induce holes or lesions in the cell membrane of tumor cells. Nontoxic effects of the immune system involve modification of cell mobility (important in metastasis and loss of contact inhibition). Although many natural protective measures are built into the immune system, genetic and predisposing factors can affect tumor resistance. (27 refs)

78-6691 Evolutionary Development of IgE and the Role of Anaphylactic-Type Reactions in Resistance to Solid Tumors. (Eng) Lynch, N. R. (Institut de Recherches Scientifiques sur le Cancer, B.P. N 8, 94800 Villejuif, France); Salomon, J. C.; Turner, K. J. *Cancer Immunol Immunother* 4(4): 223-228; 1978.

The evolutionary development of IgE and the role of anaphylactic reactions in resistance to solid tumors are reviewed. The necessary components for allergic or anaphylactic-type reactions are found in many species, including marsupials, which have long diverged from the main mammalian line. This finding suggests that the existence of such reactions has been evolutionarily conserved, and thus may have a regulatory or protective role in the organism. Evidence suggests that anaphylactic-type reactions are a constituent of anti-tumor mechanisms is presented. These reactions can increase the access of immune effectors into solid tumors, though progressively growing tumors appear to have a self-protective mechanism inhibiting such reactions. It has not yet been established that the anaphylactic system directly modulates the activity of lymphoid cells, although involvement in the expression of delayed hypersensitivity seems certain. The possibility that anaphylactic-type reactions contribute to parasite rejection is an attractive but controversial idea. (79 refs)

78-6692 Immunology of Rat Hepatic Neoplasia. (Eng) Baldwin, R. W. (Cancer Res. Campaign Lab., Univ. Nottingham, Nottingham, England). In: *Rat Hepatic Neoplasia: Workshop on Rat Liver Neoplasia held by William F. Merrell, Co. in Woods Hole, October, 1974*. William F. Merrell, Co. (Woods Hole, MA): 288 pp.; 228-240; 1978.

The expression of tumor-associated rejection antigens, tumor-specific cell-surface antigens, and tumor-associated embryonic antigens in carcinogen-induced rat liver tumors is discussed. The most significant characteristic of carcinogen-induced tumors is expression of the tumor-specific cell-surface antigens that may function as tumor-rejection antigens. This type of neoantigen is not always expressed by transformed cells and cannot be used as a criterion of malignant change. However, there are few exceptions to the general finding that each tumor has a characteristic antigen, and characterization of this specificity may be useful in evaluating the role of carcinogenic agents in transformation. Embryonic antigen expression may be a concomitant effect of neoplastic change; thus, typing of these antigens could provide a suitable preliminary screening assay for carcinogen-induced transformation. The role of these antigens in tumor rejection is unresolved, but it is unlikely that they are responsible for

ity elicited against transplanted hepatic tumors. (31 refs)

693 **On the Pathogenesis of Cutaneous Malignant Lymphoma (CML).** (Ger) Steigleder, G. K. Universitat Hautklinik Koln, Joseph-Stelzmann-Strasse 9, Koln 41, W. Germany). *Z Hautkr* 53(20): 719-726;

Previously published suggestion concerning the pathogenesis of cutaneous malignant lymphoma (CUML) is discussed. This suggestion still appears valid in view of current observations. Both T- and B-cell lymphomas of the skin have been reported. The suggested model of CUML development involves proliferation of lymphocytes stimulated by persistent injury or chronic exposure to UV light; if a lymphocyte contains neoplastic information, a clone of neoplastic cells will arise. The stimulated lymphocytes secrete lymphokinin, which influences other cells (eg, by decreasing the movement of macrophages). Because T-lymphocytes are more common than B-lymphocytes, neoplastic transformation of T-lymphocytes is more probable. Mycosis fungoides (MF) can be regarded as analogous to eczema, while B-cell CUML can be considered a type of exanthema. The involvement of allergic allergy is consistent with the association of MF with occupations such as construction work and others leading to sun exposure. In this model, infectious mononucleosis is considered a pseudolymphoma. (43 refs)

694 **Antigenic Changes in the Transformed Cell.** (Eng) Lennox, E. S. (MRC Lab. Molecular Biology, Hills Road, Cambridge CB2 2QH, England); Sikora, I. *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, W. Germany): 314 pp.; 197-207; 1977.

The effect of the immune system on antigenic changes in the surface components of transformed cells was studied. Tumor antigens are defined by various modes of immune response: (1) in vivo by induction of transplantation immunity or delayed-type hypersensitivity and in vitro by serological or cell-mediated reactions against tumor cells as targets. By comparing these separate modes of response, various antigens can be defined on the same tumor. The following antigens can be detected on tumor cells, some unique, some shared with normal cells: (1) normal transplantation antigens (the targets of immune rejection reactions when tissue is transplanted between individuals); (2) tumor-specific transplantation antigens (TSTA: defined in protection assays in which animals immunized with the tumor are subsequently challenged with the same or other tumors, with studies revealing that certain induced tumors carry unique TSTA); (3) virus-determined antigens (those of DNA and RNA tumor viruses; they can serve as transplantation antigens as well as immunogens for antibody formation and thus may be targets of humoral as well as cell-mediated attack); (4) embryonic

antigens (defined by antisera prepared in syngeneic animals by injection of preparations of mid-term embryos or by sera from multiparous animals; they can detect antigens on tumor cells transformed by viruses or induced by carcinogens); and (5) differentiation antigens (those present on most cells of one particular individual). TSTA appear to be the most likely candidates for recognition in immune surveillance, and they may play a major role in the interaction between the immune system and cells undergoing transformation. (12 refs)

78-6695 **Immunodeficiency and the Pathogenesis of Lymphoma and Leukemia.** (Eng) Louie, S. (Tufts Univ. Sch. Medicine, Boston, MA, 02111); Schwartz, R. S. *Semin Hematol* 15(2): 117-138; 1978.

The possible pathogenic connection between immunologic abnormalities and malignant lymphoproliferative diseases is examined in light of clinical situations associated with a high risk of lymphoma. Several congenital immunodeficiency diseases are associated with a high risk of malignant lymphoma: ataxia telangiectasia, Wiscott-Aldrich syndrome, common variable immunodeficiency, and Bloom's syndrome. A characteristic of all these diseases is the presence of abnormalities outside the immune system, and the genetic disturbance in these conditions can manifest itself by structural changes in chromosomes. These diseases may be regarded as premalignant states characterized by chromosome instability and an associated immunologic disturbance. The risk of developing malignant lymphoma is also increased in recipients of renal allografts and in untreated patients with certain immunoinflammatory diseases (autoimmune hemolytic anemia, Sjogren's syndrome). The risk of developing acute myelogenous leukemia is increased in patients treated with immunosuppressive agents for immunoinflammatory diseases and in cancer patients treated with either aggressive chemotherapy or chemotherapy combined with radiotherapy. It is suggested that some 'spontaneous' lymphomas may arise as the result of the enhanced proliferation of mutant lymphocytes brought about by the selective pressure of impaired immunoregulation. (164 refs)

78-6696 **Geographical Distribution of Gastrointestinal Cancer and Breast Cancer and Its Relation to Selenium Deficiency.** (Eng) Jansson, B. (Natl. Large Bowel Cancer Project, Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Mahaly, M. A.; Seibert, G. B. *In: Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1161-1178; 1977.

Evidence indicating that selenium may act as an inhibitor of cancer of the colon, rectum, and breast is reviewed. Studies in the US and New Zealand showed that low rates of colon, rectal, and breast cancer were associated with high Se concen-

trations in the soil and vice versa. A New Zealand veterinarian observed that the incidence of intestinal adenocarcinomas and other neoplasms in sheep was reduced after the introduction of Se drenching. Similar findings were obtained in studies of rats fed carcinogens with and without Se. Another study showed that spontaneous mammary tumors were inhibited by Se in mice. An unexpected finding was that the incidence age was lowered for tumor-bearing mice fed Se compared with untreated control tumor-bearers. Se deficiency reduces the fertility of animals and may also have the same effect in humans. Thus, the finding of a negative correlation between birth rates and colon, rectal and breast cancer rates in a study of the natality and mortality statistics for 48 continental states further supports the hypothesis that Se or some other agent acts as an inhibitor of these cancers. (38 refs)

- 78-6697 **Causes of Cancer in Man.** (Eng) Miller, R. W. (NCI, NIH, Bethesda, MD, 20014). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 25-38; 1977.

The causes of cancer in humans are reviewed, with emphasis on physical and chemical carcinogens. Among the physical carcinogens are two forms of radiation, ionizing and UV. Ionizing radiation can penetrate deeply and induce various forms of cancer, whereas UV light is not penetrating and induces only skin cancer. Asbestos acts as a physical carcinogen in that its physical properties, ie, the length and diameter of the fibers, apparently account for its carcinogenicity in various organs. Chemical carcinogens induce respiratory tract, urinary bladder, blood, and liver malignancies, especially in heavily exposed industrial workers. A subtle influence of chemical carcinogenesis early in life is indicated by the retention of old-country cancer rates in migrants whose children have the cancer rates of the new country and by the distinctive patterns of excessive mortality from specific cancers observed in the 3,056 US counties between 1950-1969. Some of these patterns appear to be related to industries within the counties. Despite extensive laboratory evidence for viral oncogenesis, no virally induced human cancers have been demonstrated. Host factors, including single genes, chromosomal aberrations, and immunodeficiency, may place individuals, families, or ethnic groups at a very high or low risk of certain cancers. (33 refs)

- 78-6698 **Variations in Cancer Death Rates.** (Eng) Lew, E. A. (Dept. Epidemiology and Statistics, American Cancer Society, Inc., New York, NY). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1127-1138; 1977.

Current observations of the variations in cancer death rates among various populations are reviewed briefly, with a warning directed against premature overzealous interpretation of apparent differences. Although US death rates increased 5.2% in the first 7 mo of 1975, the age-adjusted death rate actually increased only approx 1% over the entire yr. It has been an observable phenomenon, however, that sharp increases are noted in cancer death rates over the first half of any year. Comparisons among nations must be made with care, particularly when 10-fold differences in population exist, eg, the US and Sweden. Moreover, methods of death certification and registration vary from country to country, automatically introducing bias. It is suggested that it may be at least as useful to study mortality rates from different parts of the US as to compare different countries. Several special studies investigating social factors are discussed; in general it has been found that death rates from most cancers are higher for the lower socioeconomic classes (as defined by occupation, education, and/or economic status), although the opposite is true for prostate cancer and leukemias in men and breast cancer in women. Studies of native white vs foreign-born white vs nonwhite populations have also been useful in determining several interesting relationships, such as the increased digestive tract cancer and decreased prostate cancer mortality in these non-native populations. Better medical care facilities will continue to improve both tumor classification and the definition of various cancer incidence and mortalities. (no refs)

- 78-6699 **Our Daily Habits and Cancer.** (Swe) Werko, G. (Farmaceutisk Divisionen, Astra Lakemedel AB, Sweden). *Lakartidningen* 75(10): 919-920; 1978.

The risk of cancer is increased by tobacco, alcohol, and dietary habits. Positive correlations have been found between alcohol consumption and laryngeal and buccal cavity cancer and between high-fat diets and leukemia or colon and breast cancer. (11 refs)

- 78-6700 **Benign and Malignant Breast Tumors: Epidemiological Similarities.** (Eng) Sartwell, P. E. (Dept. Epidemiology, Johns Hopkins Univ. Sch. Hygiene and Public Health, Baltimore, MD, 21205); Arthes, F. Tonascia, J. A. *Int J Epidemiol* 7(3): 217-221; 1978.

Risk factors were estimated in 783 cases of cystic disease of the breast (CD), 155 cases of breast fibroadenoma (FA), 10 cases of miscellaneous breast conditions, and 284 cases of breast cancer. FA occurred in the youngest patients, the highest percentage (39.4%) occurring in patients aged 15-24. The cancer patients were the oldest, 67.6% of the cases occurring in women aged 45-64 yr. Relative risks were calculated for each of the four breast conditions, with respect to the possible risk factors that could be categorized dichotomously. These were nulliparity, first pregnancy at age 25 or older, being premenopausal at the time of discovery of the lesion, and marriage at age 20 or over. Each patient was compared

her own control matched for age, race, ever-married, time of hospitalization, and pay status. Risks associated with being nulliparous were all above unity, but only that the cancer patients was statistically significant ($p < 0.05$). First pregnancy at an older age, all the risks were above unity, and those for CD and cancer were significantly elevated. In all four disease classes, the patients had fewer pregnancies than their controls; the differences were significant only for CD and FA. CD patients had experienced both natural and artificial menopause less commonly than their controls; breast cancer patients had experienced only artificial menopause, more commonly than their controls. This general similarity between benign breast disease and breast cancer in certain reproductive and menstrual features plus previous evidence that breast cancer is more frequent in women who have previously had benign breast disease suggest a similarity in etiologic factors. (9 refs)

701 The "Urban Factor" and Lung Cancer: Cigarette Smoking or Air Pollution? (Eng) Carnow, J. (Dept. Preventive Medicine, Univ. Illinois, Chicago, IL 60680). *Environ Health Perspect* 22: 17-21; 1978.

Evidence that urban pollution is a significant etiologic factor in lung cancer was provided by four groups of studies. Studies of urban-rural death rates revealed a doubling of lung cancer mortality in large cities compared with rural areas, which could not be explained by a difference in smoking habits. Studies of lung cancer death rates in migrants also suggested a relationship to urban pollution. Among studies that used regression analysis in an attempt to identify urban factors responsible for urban-rural differences in death rates from lung carcinoma, one indicated that the products of solid fuel combustion may be an important etiologic factor and another showed a significant relationship between the death rates and atmospheric concentrations of (a) pyrene (BP) levels. After standardization for such variables as smoking habits, age, sex, and duration of residence, sampling studies in the US and other countries found that lung cancer incidence was significantly associated with urbanization and air pollution. Data on lung cancer deaths among coke oven workers were used to calculate a dose-response relationship between BP and lung cancer in an urban community. The risk of excess lung cancer is due to continuous exposure to BP is higher than previously assumed. (24 refs)

702 Identification of Carcinogenic Hazards from Aromatic Amine Exposures and Measures for Control. (Eng) Parkes, H. G. (Health Res. Unit, British Rubber Manufacturers' Assoc., Scala House, Holloway Circus, London, W.1, England). In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY). Vol. 2 (part 1), 2404 pp.; 1913-1920; 1978.

Variation in the duration, intensity, and conditions of occupational exposure to carcinogens such as aromatic amines will determine whether the resultant cancer incidence is 100% or negligible. Suspicions may be aroused by chemical similarities between established and suspect carcinogens and they may be reinforced by evidence of experimental mutagenicity, teratogenicity, or carcinogenicity, but positive epidemiological identification is the final confirmation of a carcinogenic hazard. (12 refs)

78-6703 Cell Cycle Dependency of Transformation. (Eng) Baserga, R. L. (Dept. Pathology, Fels Res. Inst., Temple Univ. Sch. Medicine, Philadelphia, PA, 19140). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977*. Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 125-133; 1977.

A review of the major studies concerning the cell-cycle dependency of transformation, coupled with more recent work showing a close relationship between transformation and mutagenesis, suggest that G_1 cells are more susceptible to transformation than are G_0 cells because they have a higher relative transcriptional activity, and transcriptionally active chromatin is more accessible to mutagens and carcinogens than is transcriptionally inactive chromatin. It has also been shown that S-stage cells are susceptible to transformation for the same reason G_1 cells: incorporation of the transforming agent into the accessible DNA. It may be predicted from these conclusions that G_0 cells are strongly resistant to transformation by chemical carcinogens, and research is discussed that supports this contention. (18 refs)

78-6704 DNA Polymerase and Mutation. (Eng) Bridges, B. (Univ. Sussex, Sussex, England). *Nature* 275(5681): 591-592; 1978.

Several theories on the interaction between DNA damage and DNA polymerases in the generation of permanently altered nucleotide sequences and, as a result, cancer and certain heritable diseases are presented. (4 refs)

78-6705 Cellular Susceptibility to Neoplasia and Its Reversibility. (Eng) Gardner, R. L. (Dept. Zoology, Univ. Oxford, South Parks Road, Oxford OX1 3PS, England). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a Meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977*. Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 111-124; 1977.

Cell susceptibility to neoplastic transformation and its reversibility are reviewed. The susceptibility has been proven to be

dependent on both intrinsic and extrinsic elements. Intrinsically, genetic manifestation of susceptibility is the result of polymorphic loci coding for enzymes involved in DNA repair or metabolism of carcinogens and proteins affecting the activity of tumor viruses. Among the extrinsic factors that have been implicated in neoplasia because they alter the cellular environment are chemical carcinogens, 'foreign bodies', prolonged endocrine imbalances, and other elements that impose stress on tissue homeostasis. It is suggested that all these extrinsic mechanisms act by stimulating cell division. A number of methods have been used to suppress neoplasticity; such as incorporation of a thymidine analog into DNA, use of temperature-sensitive mutant cells that are neoplastic only at the permissive temperature, or hybridization of malignant cells with nonmalignant cells that have lost a single chromosome. Differentiation of tumor cells to a terminal, postmitotic state can result in loss of neoplasticity. Furthermore, a model of plant and animal teratoma cells and nuclei isolated from adenocarcinoma cells suggests that neoplasia may in some instances also be reversed. (33 refs)

78-6706 Characterization of Hepatic Nodules. (Eng)

Becker, F. F. (Dept. Anatomic and Experimental Pathology, M. D. Anderson Hosp. and Tumor Inst., 6723 Bertner Ave., Houston, TX, 77030). In: *Rat Hepatic Neoplasia: Workshop on Rat Liver Neoplasia held by William F. Merrell, Co. in Woods Hole, October, 1974*. William F. Merrell, Co. (Woods Hole, MA): 288 pp.; 42-57; 1978.

Research on premalignant and malignant hepatic nodules is reviewed. Identification of premalignant lesions in animal tissues exposed chronically to chemical carcinogens would provide insight into the possibility of a chemical etiology for similar lesions in humans, allow analyses to be focused on one small region rather than the entire organ, and would help in understanding of characteristics of malignant cells. Evidence indicating that hepatic nodules are premalignant lesions is presented. Study of hepatic nodules allows carcinogen-altered tissue to be examined at various stages in its progression toward malignancy and nodules of different stages to be compared with each other and with nonnodular parenchymal areas. Techniques allowing cytogenetic analysis of the chromosome composition of solid hepatic tissues have been developed recently. Problems in transplanting of hepatic nodules successfully are reviewed. The hepatic nodule is the best available tissue to which new analytical techniques can be applied and upon which new oncological concepts can be tested. (35 refs)

78-6707 Sequential Cellular Alterations During Hepatocarcinogenesis. (Eng) Bannasch, P. (Abteilung

fur Cytopathologie, Institut fur Experimentelle Pathologie Deutschen Krebsforschungszentrum, Heidelberg, W. Germany). In: *Rat Hepatic Neoplasia: Workshop on Rat Liver Neoplasia held by William F. Merrell, Co. in Woods Hole, October, 1974*. William F. Merrell, Co. (Woods Hole, MA): 288 pp.; 58-99; 1978.

The sequential alterations observed in liver cells under the influence of hepatocarcinogens are discussed. Reversible alterations are characterized by a predominantly centrilobular loss of glycogen and by a concomitant dispersal of the basophilic bodies. The outstanding feature of persistent alterations is an excessive storage of glycogen, which appears to be due to the direct action of the carcinogen, resulting in an irreversible cell lesion. At the end of the preneoplastic phase in most animals, so-called hyperplastic nodules develop. These nodules appear to originate from areas storing glycogen in excess, and most nodules are probably a mixture of precancerous, cancerous, and diverse intermediary cells. It is highly probable, however, that the hyperplastic nodule is only one of at least two histologically different formations in which neoplastic transformation can take place. Nearly the entire liver parenchyma appears to undergo irreversible cellular alterations, with cellular enlargement being due mainly to excessive glycogen storage and/or a proliferation of the membranes of the agranular endoplasmic reticulum. The data suggest that the glycogen-free basophilic tumor cell is the result of a long process that begins with an excessive storage of glycogen and perhaps passes through a stage of membrane proliferation or fat accumulation. (67 refs)

78-6708 Characteristics of Malignant Phenotypes

Familial Polyposis. (Eng) Wells, S. A. (Duke

Univ. Medical Center, Durham, NC, 27710); Johnson, A. F.; Gregory, R. O. In: *International Advances in Surgical Oncology*. Murphy, G. P., ed. (New York: Alan R. Liss, Inc. Vol 1, 288 pp.; 29-52; 1978.

The clinical characteristics of various gastrointestinal polyposis syndromes, particularly familial polyposis coli (FPC), and their relationship to colorectal cancer are reviewed. FPC, which is transmitted as an autosomal dominant trait, is characterized by development in adolescence or early adult life of adenomatous polyps on the mucous membrane of the colon and rectum. The incidence of colon malignancy in FPC is thought to approach 100%. Proper therapy is contingent on distinguishing the disease from inflammatory polyps, lymphoid polyps, hamartomatous polyps, multiple neurofibromatosis (Von Recklinghausen's disease), lipomatous polyps, hyperplasia or metaplasia, and pneumatosis cystoides intestinalis. There are no serum, plasma, blood cell, or urinary markers associated with the disease. Surgery is the treatment of choice, the most common procedures being total proctocolectomy with abdominal ileostomy, total colectomy with ileoproctostomy (TC and I) (preferred), or anal ileostomy. Regression of rectal polyps occurs in approx 10%-15% of FPC patients undergoing surgery, but this phenomenon is not permanent. Other syndromes that share two common traits with FPC (autosomal dominant inheritance and propensity to develop gastrointestinal carcinoma) include Gardner's syndrome, Turcot's syndrome, familial 'minor' adenomatous polyposis coli, juvenile polyposis coli, and Peutz-Jeghers syndrome. The etiology of all these syndromes may involve genetic, environmental, and immunologic factors. (91 refs)

CHEMICAL CARCINOGENESIS

709 **Gas Standards for Air Pollution Analysis.** (Eng) Taylor, J. K. (Natl. Bureau Standards, Gaithersburg, MD); Hughes, E. E.; Dorko, W. D.; Cadoff, B. C.; Schmidt, W. P.; Marinenko, R. J.; Friend, D. G.; Meeks, S.; De, E.; Johns, R. H.; Deardorff, E. R.; Friend, D. G.; Er, B.; Heinrich, K.; Myklebust, R. *NBS Tech Note* 80-104; 1978.

Research was conducted to develop or improve methods for deriving primary gas standards for air pollution analyses by gravimetric, volumetric, and manometric techniques. Another objective was to provide the traceability of all air pollution measurements, including those concerned with the occupational environment, ambient air, and source emissions, to a common set of analytical standards. (8 refs)

710 **Applications of Infrared Measurements to Air Pollution Problems.** (Eng) Deslattes, R. (Natl. Bureau Standards, Gaithersburg, MD); Howard, C. J.; Radtke, H. E.; Lafferty, W. J.; Freund, S.; Layer, H.; Schenck, R.; Rougen, J.; Maki, A.; Beers, Y.; Evenson, K.; Wells, J.; Evove, J.; Sweger, D.; Hughes, E.; Okabe, H.; Streit, G. *NBS Tech Note* (963): 22-36; 1978.

Techniques and instrumentation were developed to utilize infrared laser devices in measuring air pollutants, particularly NO_2 and O_3 , and molecules that play a role in pollution, OH and HO_2 . The latter two molecules are radical species in the chemistry of smog formation and atmospheric ozone destruction by anthropogenic pollutants. (8 refs)

711 **In Vivo Covalent Binding of Chemicals to DNA as a Short-Term Test for Carcinogenicity** (Abstract). (Eng) Lutz, W. K. (Inst. Toxicology, Univ. Zurich, CH-8603 Schwerzenbach, Switzerland); Matter, C. *Experientia* 34(7): 927; 1978. (no refs)

712 **Effects of Vinyl Chloride in Man. A Cytogenetic Follow-up Study.** (Eng) Hansteen, I. L. (Lab. Cytogenetics, Telemark Central Hosp., Olavsgt. 26, 3900 Porsgrunn, Norway); Hillestad, L.; Thiis-Evensen, E.; Heldaas, S. *Scand J Clin Lab Invest* 51(2): 271-278; 1978.

A second cytogenetic study was made of 37/39 workers at a vinyl chloride plant 2.5 yr after a first study, during which time the workers had minimal exposure to vinyl chlo-

ride monomer (VCM). The second study, performed with 32 matched controls, was conducted to determine whether the chromosome damage found in the first study was due to VCM. Of the original 39 workers, 14 had been chosen at random, 13 because they had heavy exposure to VCM for years, and 12 because of abnormal clinical findings that later proved to be normal. Breaks, gaps, and stable rearrangements were scored as 100 metaphases/person from 48-hr lymphocyte cultures. In the first study, the mean number of chromosome breaks was significantly higher for the workers (3.41%) than for the controls (1.79%). No significant difference between these groups was found in the second study. In addition, there was no significant difference in mean number of breaks between the first control group and both groups of the second study. The results of the two studies provide evidence that VCM was the cause of the chromosome damage found in the first study. In the second study, the mean number of sister chromatid exchanges per cell was the same (7.6) for both workers and controls. (19 refs)

78-6713 **Hepatic Angiosarcoma due to Vinyl Chloride. Report of 4 Cases.** (Fre) Roche, J. (Clinique d'Hépatologie-Gastroenterologie, C.H.U. de Grenoble, Hôpital des Sablons, F 38700 La Tronche, France); Fournet, J.; Hostein, J.; Panh, M.; Bonnet-Eymard, J. B. *Gastroenterol Clin Biol* 2(8/9): 669-678; 1978.

Angiosarcomas of the liver developed in four men (aged 63, 48, 38, and 42 yr) who had worked in the production of vinyl chloride (VC) for 12, 26, 10, and 12 yr, respectively. Initial symptoms were abdominal pain in three patients and back pain (due to metastases) in one. The most constant laboratory indication was elevated serum alkaline phosphatase [55-77 milli(m)IU]; gamma-glutamyltranspeptidases were markedly elevated (217 and 298 mIU) in the two patients in which they were measured. α -Fetoprotein was normal, and SGOT and SGPT were close to normal. Two patients had hepatomegaly, which was the principal clinical finding in the literature on other VC-induced angiosarcomas. Arteriography revealed the angiosarcoma in the four patients, although $^{99\text{m}}\text{Tc}$ liver scans in two patients were also indicative of liver pathology. Gastrointestinal tract hemorrhage occurred in two patients and hemorrhage into the peritoneum in two. Survival from onset of symptoms was 2-13 mo. Clinical, biochemical, and histological features of previously reported patients with VC-induced angiosarcomas are reviewed. (50 refs)

78-6714 **Occurrence of Hepatocellular Tumors and Hemangiosarcoma in Rats Inhaled 1,2-Di-**

bromoethane Under the Influence of Disulfiram Treatment (Meeting Abstract). (Eng) Wong, L. C. (Pharmacology and Toxicology, Midwest Res. Inst., Kansas City, MO, 64110); Winston, J. M.; Hong, C. B.; Lee, C. C.; Bhandari, J. C. *Pharmacologist* 20(3): 174; 1978. (no refs)

78-6715 Chromosomal Analyses in Vinyl Chloride-exposed Workers. (Eng) Purchase, I. F. (Central Toxicology Lab., Central Medical Group and Mond Div., Imperial Chemical Industries Ltd., Alderley Park, Macclesfield, Cheshire, England); Richardson, C. R.; Anderson, D.; Paddle, G. M.; Adams, W. G. *Mutat Res* 57(3): 325-334; 1978.

The chromosomal morphology of cultured peripheral lymphocytes from 81 men [57 employed in plants manufacturing vinyl chloride (VC) or polyvinyl chloride (PVC), 19 on-site controls, and 5 off-site controls] was studied. There was a significant increase in chromosomal abnormalities among the VC/PVC-exposed workers compared with the controls. Total B cells (those with a chromatid break or gap or a chromosome gap), total Cu cells (those with larger unstable chromosomal abnormalities), and total Cs cells (those with larger unstable chromosomal abnormalities) showed the greater increases in autoclave operators, with smaller increases in the other five job categories. The increase in chromosomal aberrations was correlated with length of exposure and with a history of exposure to short-term excursion levels (approx 15 ppm) of VC during the year prior to sampling (1973-1974). There were no correlations between results of liver function tests and chromosome aberrations. Quantity of tobacco smoked 18 mo after blood sampling was correlated with total C cells, as was smoker vs nonsmoker status at 18 mo postsampling. It was not possible to determine whether smoking history, length of employment, or exposure to short-term excursion levels of VC was the most important variable in determining C-cell abnormalities. 78-6716 Use of Terbium(III) Fluorescence Enhancement to Selectively Monitor DNA and RNA Guanine Residues and Their Alteration by Chemical Modification. (Eng) Ringer, D. P. (Biomedical Div., Samuel Roberts Noble Foundation, Ardmore, OK, 73401); Burchett, S.; Kizer, D. E. *Biochemistry* 17(22): 4818-4825; 1978.

The abilities of DNA and ribosomal RNA (rRNA) from rat liver to enhance terbium(III) (Tb^{3+}) fluorescence were studied under aqueous conditions at pH 6 and at room temperature. DNA and rRNA excited by 290-nanometer light enhanced Tb^{3+} fluorescence by 1,800-fold and 13,000-fold, respectively. Of various ribose and deoxyribose nucleotides examined, only those containing guanine, guanosine 5'-monophosphate (Guo-5'-P) and deoxy-Guo-5'-P, produced significant enhancement of fluorescence. Similarly, only po-

ly(G) of the homopolymers of the four common ribonucleotides was a strong enhancer to Tb^{3+} fluorescence. The Guo-5'-P moiety in the polymer state was at least five to six times more efficient in increasing fluorescence than the free nucleotide. No enhancement was produced with 7-methyl-Guo-5'-P or Guo-5'-P modified at the 1 and N² positions by kethox and at the 8 position by N-acetoxy-2-acetylaminofluorene (NA-AAF). Chemical modification of rat liver DNA and rRNA in vitro with NA-AAF resulted in a 70% and 30% respectively, reduction in their ability to enhance Tb^{3+} fluorescence. Thus, Tb^{3+} may be useful as a guanine-specific fluorescent probe for RNA and DNA. Also, since modifications at several different positions on guanine caused loss of enhancing ability, the terbium probe may be useful in detecting guanine modifications. (40 refs)

78-6717 Chemical and Toxicological Studies on Bracken Fern, *Pteridium aquilinum* Var. *latiusculum*. I. Introduction, Extraction and Fractionation of Constituents, and Toxicological Studies Including Carcinogenicity Tests. (Eng) Yoshihira, K. (Natl. Inst. Hygienic Science, Kamiyoga-1-Chome, Setagaya-ku, Tokyo, Japan); Fukuo, M.; Kuroyanagi, M.; Natori, S.; Umeda, M.; Morohoshi, T.; Enomoto, M.; Saito, M. *Chem Pharm Bull (Tokyo)* 26(12): 2346-2364; 1978.

Twenty-four pterosins and related compounds isolated from Bracken Fern, *Pteridium aquilinum* var. *latiusculum*, were tested for toxicity in HeLa cells and experimental animals. Young fronds and rhizomes were collected from various sites, extracted with organic solvents and/or water, and, in some cases, further purified by column and thin-layer chromatography. Typical isolates were a group of C₁₄ or sesquiterpenoids with a 1-indanone nucleus, termed pterosins, and their related glucosides and pterosides. Several compounds produced morphologic changes in HeLa cells within test samples for 3 days. In animal toxicity tests, the compounds were administered to DDD mice, Wistar male rats, and male Hartley guinea pigs by feeding (5 or 15 g/day), injection (0.2 or 0.3 ml/20 g), or gastric intubation (0.4 ml/g). Four of the pterosins were toxic for the mice as were several crude bracken fractions. A frequent finding was injury to actively dividing cells, including involution of thymus and cytotoxic changes in the lymph follicles and crypts of the small intestine. Long-term carcinogenesis feeding experiments were undertaken in male Wistar and Fischer rats, with 4-340 mg/day of fern isolates added to their diet for 35-205 days. Crude extracts of fronds and rhizomes induced tumors preferentially in Fischer rats, particularly in the ileum, but purified fractions and extracts did not. Ileal tumors included adenomas and papillary carcinomas. (49 refs)

78-6718 Comparison of the Oncogenicities of Four Structurally Isomeric N-Hydroxyanthrins

Teller, M. N. (Donald S. Walker Lab., Sloan-Kettering Cancer Res., 145 Boston Post Road, Rye, NY, 10580); Jinger, J. M.; Zvilichovsky, G.; Watson, A. A.; McDon-J. J.; Stohrer, G.; Brown, G. B. *Cancer Res* 38(7): 2042; 1978.

oncogenicities of all of the four possible isomeric hydroxyxanthines were compared in rats. 3-Hydroxyxanthine induced sarcomas in 88%-100% of the rats when administered sc at a dose of 1 mg 3x/wk for 8 wk; at a dose of 0.1 mg (same route and schedule), both sarcomas and fibromas appeared in 25%-58% of the rats given the isomer. Total 3-hydroxyxanthine doses ranging from 12-66 mg/rat induced sc tumors in 25%-100% of the rats, some of which also developed hepatocellular carcinomas. The oncogenicity of 7-hydroxyxanthine approached that of the 3-isomer, particularly in the induction of liver tumors. At 1 mg given 3x/wk for 8 wk, the 7-isomer induced both sc and liver tumors in 40% of the rats compared with 89% for the 3-isomer. Liver tumors were induced in 45% and 65% of the rats given 1.0-mg ip injections (3 x/wk for 8 wk) of the 7- and 3-isomers, respectively. The difference was not significant. 9-Hydroxyxanthine showed no oncogenicity, which is the result of the stability of its sulfate ester. 1-Hydroxyxanthine was not oncogenic in assay; it has induced tumors at doses > 1.0 mg, but there is no explanation for its oncogenicity by any correlation of chemical properties with those of the 3- and 7-isomers. (25 refs)

19 **The Tumor Promoting Action of Diterpene Esters In Vivo Correlates with Their Potency to Release Prostaglandins from Macrophages In Vitro (Meeting Abstract).** (Eng) Brune, K. (Dept. Pharmacology, Birmum, CH-4056 Basel, Switzerland); Hecker, E. *Experientia* 34(7): 922; 1978. (no refs)

720 **Snuff and Cancer of the Oral Cavity.** (Swe) Axelsson, T. (Institutionen for oral kirurgi, Lunds universitet, S-214 21 Malmo, Sweden); Mornstad, H.; Sundin, B. *Lakartidningen* 75(22): 2224-2226; 1978.

The relationship between snuff and oral cancer was studied in a series of 375 oral cancer patients found in Sweden during 1971. Forty-one patients admitted using snuff at the time of diagnosis, 8 had been snuff-dippers, 18 denied ever using snuff, and 109 admitted using tobacco in other ways; there were no data on tobacco use for 199 patients. A relationship between snuff and cancer was documented in 14 patients and found probable in 19. In 67.3% of the verified snuff-dippers, the cancer was localized to regions of the oral cavity where the snuff had been placed. Most patients, both in the entire group and the snuff-dippers, were in the age bracket 40-80 yr. The percentage of snuff-related tumors increased with advancing age. The findings indicate that snuff-dipping

increases the cancer risk at the site where the snuff is placed five- to sixfold. (7 refs)

78-6721 **The Role of Aflatoxin in Primary Liver Cancer (Meeting Abstract).** (Eng) Pang, R. T. (Dept. Internal Medicine, Univ. Indonesia, Jalan Tanah, Abang Enpat, Indonesia). In: *Summary Program and Abstracts of Papers. Proceedings of the 3rd Asian Cancer Conference Held by the Philippine Cancer Society under the Auspices of the Asian Federation of Organizations for Cancer Research and Control in Manila, 26-30 September, 1977.* Philippine Cancer Society. 78-6722 **Liver Carcinogenesis in Rats after Aflatoxin B₁ Administration. A Light- and Electron-Microscopic Study.** (Eng) Novi, A. M. (Pathologisches Institut, Universitat Dusseldorf, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany). *Curr Top Pathol* 65: 115-163; 1977.

Changes induced in the liver of female Wistar II rats by aflatoxin B₁ (AFB₁; 25 µg/day, 5 days/wk for 8 wk, by gastric intubation) were examined by light (LM) and electron microscopy (EM). Animals were sacrificed weekly during the first 8 wk and then at various intervals up to 66 wk. By 16 wk, only an increased number of megalocytes was detected by LM. EM revealed profound changes in the liver parenchyma. Depending on their location within the liver lobule, hepatocytes underwent two main patterns of modification. While periportal hepatocytes rapidly degenerated, more peripherally located parenchymal cells first showed a high proliferation of the endoplasmic reticulum, similar to that seen in hepatocytes engaged in drug metabolism; then they underwent degeneration in a pattern similar to that seen in the periportal cells. The endoplasmic reticulum was affected first, followed by depletion of glycogen and alteration of Golgi zones and then by damage to mitochondria and the cell membrane. Between 17 and 37 wk, LM revealed the appearance of small periportal foci of newly born hepatocytes that subsequently degenerated and a progressive disappearance of megalocytes. Sublobular changes resembling those seen previously were seen by EM. After 42 wk, LM showed a diffuse proliferation of periportal hepatocytes, which resulted in the appearance of islands of neoplastic cells. Degenerative changes in the new hepatocytes consisted either in addensations of their basophilic cytoplasm toward the periphery of the cell or in vacuolation of their cytoplasm. EM revealed changes corresponding to those observed at the cellular level. Thus, the lag time preceding the appearance of recognizable cancer is characterized by a constant spectrum of ultramicroscopic changes. Since the cells showed identical phenotypical changes after AFB₁ was discontinued, it is postulated that the cells have an endogenous mechanism for the storage and release of AFB₁. (49 refs)

s Fed 2-Acetylaminofluorene Followed by Phenobarbital. (g) Pugh, T. D. (Dept. Pathology, Univ. Wisconsin Sch. Medicine, Madison, WI, 53706); Goldfarb, S. *Cancer Res* 38(12): 4450-4457; 1978.

attempt was made to characterize the hyperplastic hepatocellular islands that develop during chemical carcinogenesis and to determine whether hepatocellular carcinomas develop from progenitor cells through a sequential process. Buffalo rats 30 days old were fed a 30% protein diet containing 0.02% 2-acetylaminofluorene (2-AAF) for 4 wk followed by 0.05% phenobarbital in the same diet for 39 wk, a combination that induced hepatocellular neoplasms in 5/6 and 195 phenotypically altered islands. To determine relations between cell replication rates and other traits of islands, ³H-thymidine-labeling indices and the activities of three enzymes were studied in serially cut cryostat sections. The enzymes were ATPase, glucose-6-phosphatase (G6P), and γ -glutamyl transpeptidase (GGT). Among the islands, 89% were GGT+, 71% were ATP-, and only 35% were G6P+; those islands with variations in all three enzymes had significantly higher ³H-thymidine-labeling indices than islands with only one or two variations. The acquisition of GGTase activity was the best marker for hyperplastic islands, although decreased G6P activity characterized a small subpopulation of islands with higher rates of cell replication. It is concluded that the increasing phenotypic diversity of islands associated with increasing rates of cell replication supports the clonal hypothesis of carcinogenesis. (15 refs)

78-6730 Mechanism of In Vitro Mutagenic Activation and Covalent Binding of N-Hydroxy-2-Acetylaminofluorene in Isolated Liver Cell Nuclei from Rat and Mouse. (Eng) Sakai, S. (Biochemical Pharmacology Section, Lab. Chemical Pharmacology, Developmental Therapeutics Program, Div. Cancer Treatment, NIH, Bethesda, MD, 20014); Reinhold, C. E.; Thorgeirsson, S. S. *Cancer Res* 38(7): 2820-2826; 1978.

in vitro mutagenic activation (MA) of N-hydroxy-2-acetylaminofluorene (N-OH-AAF) in *Salmonella typhimurium* strain TA1538 by isolated rat and mouse liver cell nuclei and the in vitro covalent binding of N-OH-AAF to nuclear nucleic acids and proteins were studied. Mutagenic MA of N-OH-AAF and 2-acetylaminofluorene by liver cell nuclei was observed. The MA of N-OH-AAF by mouse nuclei was 6-7 times greater than that by rat nuclei (2,300 vs 350 revertants/10 μ g N-OH-AAF). The mutagenicity of N-OH-AAF was increased twofold when NADPH was included with the nuclei; this increase was inhibited by α -naphthoflavone. The carboxylesterase:amidase inhibitor paraoxon (10^{-5} M) completely inhibited the MA of N-OH-AAF in the 100,000 g supernatant from rat liver (RLS), whereas 50% inhibition of N-OH-AAF mutagenesis was observed when adenosine 3'-phosphate 5'-phosphosulfate was added to the

RLS. The addition of RLS to mouse liver nuclei resulted in a decreased mutagenicity of N-OH-AAF that could be further inhibited by paraoxon. On the other hand, the addition of this supernatant to rat liver nuclei resulted in an increase in N-OH-AAF mutagenicity that was insensitive to inhibition by paraoxon. Vitamin E and butylated hydroxytoluene (10^{-2} M) inhibited the MA of N-OH-AAF by 20%-30% in the mouse nuclear preparation, whereas vitamin C at the same concentration increased N-OH-AAF mutagenesis two- to threefold. Addition of cysteamine and methionine (10^{-2} M) to the mouse nuclear preparation resulted in 60% and 30% inhibition, respectively, of N-OH-AAF mutagenesis. The first step in the in vitro MA of N-OH-AAF by isolated rat and mouse liver cell nuclei and/or RLS and the in vitro covalent binding of N-OH-AAF to nuclear nucleic acids and protein occur primarily via deacetylation of the carcinogen by either the membrane-bound amidase or the N,O-acyltransferase in the supernatant fraction. (48 refs)

78-6731 Metabolism of 2-Acetylaminofluorene in Primary Cultures of Rat Hepatocytes (Meeting Abstract). (Eng) Spilman, S. D. (Dept. Environmental Toxicology, Univ. California, Davis, CA, 95616); Byard, J. L. *Pharmacologist* 20(3): 175; 1978. (1 ref)

78-6732 Influence of Chemical Carcinogens on the Physiological Effects of Adrenomimetics. (Rus) Gurkalo, V. K. (Lab. Chemical Carcinogens, N. N. Petrov Res. Inst. Oncology, Leningrad, USSR); Pliss, G. B. *Vopr Onkol* 24(4): 49-53; 1978.

The carcinogen-induced activation of α - and β -adrenoreceptors was studied in isolated rat and guinea pig atria. Exposure of the atria to the hepatocarcinogens 2-acetylaminofluorene (AAF: 1 μ g/ml) or diethylnitrosamine (DENA: 0.01 μ g/ml) increased the rate and amplitude of spontaneous contractions. At large concentrations, AAF and DENA (10-50 and 1-10 μ g/ml, respectively) inhibited the spontaneous contractions completely. AAF selectively inhibited the inotropic effect of norepinephrine in rat atria, but not in guinea pig atria. DENA had a similar effect on rat and guinea pig atria. In rat atria, sensitivity to noradrenaline decreased with increase in AAF concentrations. (15 refs)

78-6733 Nitrates and Nitrites in the Human Diet (Letter to Editor). (Eng) Hartman, P. E. (Mergenthaler Lab. Biology, Johns Hopkins Univ., Baltimore, MD, 21218). *Science* 202(4365): 260; 1978.

Of the gastric nitrite in healthy individuals, 28% is probably derived from cured meats as opposed to the < 20% quoted previously. Cured meats are suspect teratogens, and strong correlations have been demonstrated between nitrite ingestion, gastric nitrite, and stomach cancer. Heavy fertilization

may be increasing the nitrate content of spinach and tomatoes. (10 refs)

- 78-6735 Studies on the Immunological Response in Rats with Experimental Urinary Bladder Carcinoma.** (Jpn) Nishijima, T. (Dept. Urology, Osaka City Univ. Medical Sch., Osaka, Japan). *Jpn J Urol* 69(8): 1044-1054; 1978.

Experimental bladder tumors were induced in Wister rats by po administration of 0.025% N-butyl-N-(4-hydroxybutyl)nitrosamine (BBN), and changes in the bladder histopathology and in the mitogen response of lymphocytes with time were investigated. There were no significant differences in body wt between the experimental and control groups. However, there was a significant increase in bladder wt and a significant decrease in thymus wt ($p < 0.01$) in the experimental group. At 12 wk after BBN administration, hyperplasia began to develop in the bladder mucous epithelium; there was gradual growth in a papillary form and, after 24 wk, transitional cell carcinomas were found in all rats. The stimulation index values of the lymphocytes from the cervical and mesenteric lymph nodes began to decrease significantly ($p < 0.005$) from the time hematuria was observed macroscopically (about 21 wk after BBN treatment), but there were no significant differences between the responses to phytohemagglutinin (PHA) and concanavalin A (Con A). The SI values of the thymic lymphocytes decreased significantly ($p < 0.01$) from the time hyperplasia was found in the bladder mucous membrane (about 15 wk), before the significant reduction in the mitogen responses of lymph node lymphocytes. The decrease was much greater with Con A than with PHA stimulation. (55 refs)

- 78-6736 Malignancies Associated with Immunosuppressive or Cytotoxic Therapy.** (Eng) Penn, I. (Dept. Surgery, Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO, 80220). *Surgery* 83(5): 492-502; 1978.

The increased risk of malignancy in five groups of patients receiving immunosuppressive or cytotoxic therapy is discussed. There is a 36% incidence of neoplasia in transplant recipients who received organs from donors with cancer. Transplant patients have a 6% risk of developing de novo tumors at some time after transplantation; this frequency is 100 times greater than that for the general population in the same age range. Patients who undergo transplantation as treatment for malignancies have variable recurrence rates: 62.5% following liver replacement for hepatic malignancies, and 31% after bone marrow grafting for acute leukemia. The

treatment of renal malignancies by kidney transplantation has a 53% recurrence rate if the interval between treatment of the cancer and transplantation is ≤ 1 yr; no recurrence have been noted with longer waiting periods. Neoplasms have also occurred in nontransplant patients treated with immunosuppressive agents. Cancer patients treated with chemotherapy may subsequently develop second or third tumors. A statistically significant increase in the incidence of acute myeloid leukemia has been noted in patients given cytotoxic therapy for multiple myeloma, Hodgkin's disease, and ovarian cancer. Thus, immunosuppressive and cancer chemotherapeutic agents should be used with caution, and the long-term use of immunosuppressive agents in nontransplant patients with nonmalignant disease should be restricted to those in whom all other forms of therapy have failed. (10 refs)

- 78-6737 Depression by Ethionine of Phosphorylation and Oxidation in Hepatic Mitochondria.** (Eng) Higgins, E. S. (Dept. Biochemistry, Medical Coll. Virginia, Virginia Commonwealth Univ., Richmond, VA, 23298); Friend, W. H.; Rogers, K. S. *Experientia* 34(5): 578-579; 1978.

The immediate effect of ethionine on the ATP generating capacity of male Sprague-Dawley rat hepatic mitochondria was investigated in vivo and in vitro. The induction of hepatic steatosis and the suppression of hepatic ATP levels, protein synthesis, and gluconeogenesis subsequent to ethionine administration may be consequences of its interference with the mitochondrial phosphorylation of ADP. The mitochondrial dysfunction is not a direct action of ethionine on the organelle. (19 refs)

- 78-6738 Saccharin, Cancer, and Calories (2 Letters to the Editor).** (Eng) Campbell, T. C. (Federation of American Societies Experimental Biology, Bethesda, MD 20014). *Science* 202(4365): 260-262; 1978.

In comments on a report based on estimates of the Food and Drug Administration (FDA) linking bladder cancer to saccharin ingestion, species differences in response to carcinogens are discussed. The responses can vary by three or four orders of magnitude. The assumption that noncaloric sweeteners reduce calorie consumption is also questioned. In reply, the FDA's risk estimate is also questioned and several examples of how uses of saccharin do decrease calorie intake are cited. (6 refs)

- 78-6739 Histological Conformity of Implantation Tumors Produced by Kidney Cell Lines Derived from Dimethylnitrosamine-treated Rats with Dimethylnitrosamine-induced Renal Mesenchymal Tumors.** (Eng) Hard, G. C. (Fels Res. Inst., Temple Univ. Sch. Medicine)

Philadelphia, PA, 19140). *Cancer Res* 38(7): 1974-1978; 1978.

Histology of five implantation tumors induced in Wistar by the deposition of cultured cell lines derived from diethylnitrosamine (DMN)-treated rats is described and compared with the morphology of the predominant kidney plasma induced in vivo by a single high dose (60 mg/kg) of DMN. The cell lines leading to growth upon implantation of long-established, continuously growing cultures obtained from either a DMN-induced renal mesenchymal tumor or from rats treated shortly (2 hr) before with a carcinogenic dose (60 mg/kg) of DMN. The latter cultures expressed morphological transformation at subcultures 5 or 6. All of the implantation tumors were of the mesenchymal type, comprising a range of cell forms that included fibroblastlike spinules, smooth muscle fibers, and giant cells, which resembled common aspects of the parent mesenchymal tumors induced in the rat kidney by DMN. The deposition of cells renally illustrated the survival of remnants of preexisting neoplasms as epithelial profiles scattered through the proliferating malignant tissue, a feature most characteristic of the parent tumor. The results confirmed the malignant nature of the various cell lines tested, and they were consistent with the premise that the in vivo-in vitro system selected cells in culture that represented the same target population from which the renal mesenchymal tumors were derived in vivo. 7740 Macroautoradiographic Study of the Distribution of ^{14}C -Dimethylnitrosamine in Mice and Rats. (Eng) Takahashi, G. (Dept. Pathology, Chest Disease Res. Inst., Kyoto Univ., Kyoto, Japan). *Bull Chest Dis Inst Kyoto Univ* 11(1/2): 81-85; 1978.

Dimethylnitrosamine (DMN: 5 μCi) was administered intravenously to pregnant ICR mice on day 18 of gestation, and the distribution of radioactivity in the mice and their fetuses was determined by macroautoradiography of serial sagittal sections. Intense radioactivity was noted 30 min after intravenous administration in the liver, kidneys, bone marrow, glandular organs, skin appendages, pancreas, mucous membranes of the oral cavity, intestines, and glandular stomach. This pattern was maintained for up to 2 hr. The distribution of radioactivity was similar 30 min after per os administration of the carcinogen with intense labeling noted primarily in the liver, kidney, spleen, and pancreas. Labeled DMN or its metabolites passed through the placenta and were evenly distributed in fetal liver, intestines, bone marrow, and thymus. Because the in vivo carcinogenic activity of DEN is due to its demethylated metabolites, a comparison of radioactive label concentration in tissue susceptibility to DMN has limited value. (18 refs)

7741 Occurrence of Methylguanidine and Agmatine in Foods. (Eng) Kawabata, T. (Dept. Biomed-

ical Res. Food, Natl. Inst. Health, Tokyo, Japan); Ohshima, H.; Ino, M. *IARC Sci Publ* (19): 415-423; 1978.

Various fresh and processed foods were analyzed by a new series of methods for the presence of two mutagenic guanidino compounds, nitrosated methylguanidine (MG) and nitrosated agmatine (AG). The methods consisted of trichloroacetic acid extraction, separation of the extract into fractions by ion-exchange chromatography, colorimetric analysis of each fraction, and identification of the compounds by gas chromatography-mass spectrometry. Sixty-five fresh and smoked or cured fish and meat samples were analyzed. MG was not detected or was negligible in all samples except in three smoke-dried fish products: skipjack (178 mg/kg), chubmackerel-horse mackerel mixture (56 mg/kg), and sardines (37.8 mg/kg). These seasoning products, which are declining in use, are only used in small quantities and cannot be related to the high gastric cancer incidence in Japan. Relatively high AG levels (mg/kg) were found in fresh abalone and top shell (40-240) and in some processed fish, including fresh Alaskan pollack roe (72.5), salt-dried herring (217), salted squid (650), dried filefish (112), and smoked scallops (44.8). It is suggested that the high MG levels found in earlier food studies were due to the use of metallic salts, which catalyzed the oxidation of creatine or creatinine to give MG as an artifact. 78-6742 Ornithine Decarboxylase and Polyamines: Relationship to N-Nitrosamine Carcinogenesis. (Eng) Farwell, D. C. (Univ. New Hampshire, Durham, NH). *Diss Abstr Int B* 39(2): 706; 1978. (no refs)

78-6743 Effects of Carcinogenic and Non-carcinogenic Chemicals on Plasma Esterases in BALB/c Mice. (Eng) Tyndall, R. L. (Biology Div., Oak Ridge Natl. Lab., Oak Ridge, TN, 37830); Clapp, N. K.; Davidson, K. A.; Colyer, S. P.; Burtis, C. A. *Chem Biol Interact* 23(2): 159-169; 1978.

Esterase profiles of plasma from female BALB/c mice treated with a variety of carcinogenic, weakly carcinogenic, and non-carcinogenic chemicals were analyzed to determine whether these chemicals produce esterase alterations similar to those of diethylnitrosamine and butylated hydroxytoluene and if such alterations are more sensitive indicators of these chemicals than standard clinical chemistry tests. Mice that received diethylnitrosamine (40 mg/liter), dinitrosopiperazine (100 mg/liter), dipropylnitrosamine (100 mg/liter), dimethylhydrazine (50, 100, or 800 mg/liter), urethane (10,000 mg/liter), or dimethyldinitrosopiperazine (50, 100, or 800 mg/liter) in their drinking water for 7 days had similarly altered plasma esterase profiles. These consisted of increased activity in four esterase bands. The increased activity persisted in some bands after cessation of carcinogen exposure. Exposure to high concentrations of the weakly carcinogenic or

noncarcinogenic compounds nitrosohydroxyproline (100 mg/liter), nitrosomethoxymethylamine (100 mg/liter), 1-nitroso-4-methylpiperazine (100 mg/liter), nitroso-2,6-dimethylpiperidine (100 mg/liter), or ethyl methanesulfonate (200 mg/liter) caused no obvious plasma esterase alterations. Carbon tetrachloride ingestion (800 mg/liter) increased the activity in one esterase band and decreased the activity in a second band. Analysis of serum from test mice for levels of SGOT, alkaline phosphatase, lactate dehydrogenase-lactate substrate, and *D*- γ -glutamyl transpeptidase did not differentiate between mice treated with selected carcinogens and those treated with noncarcinogens and/or carbon tetrachloride. (33 refs)

- 78-6744 Low Level of Unscheduled [³H]Thymidine Incorporation into Hyperplastic Nodule and Hepatoma Cells after Exposure to Dimethylnitrosamine In Vivo.** (Eng) Ogawa, K. (Dept. Pathology, Sapporo Medical Coll., S.1, W.17, Chuo-ku, Sapporo 060, Japan); Enomoto, K.; Yoshida, Y.; Onoe, T. *Chem Biol Interact* 23(2): 259-262; 1978.

In order to investigate why hyperplastic liver nodules that arise prior to and with hepatoma development are resistant to the cytotoxic and growth inhibitory effects of various hepatocarcinogens, the effect of *in vivo* exposure to dimethylnitrosamine (DMN) was investigated in male Wistar rats bearing these lesions. The lesions had been induced by continuous administration of diethylnitrosamine in the drinking water (6 mg/kg/day) for 4 wk or by 3'-methyl-4-(dimethylamino)azobenzene in the diet (0.06%) for 12 wk. They were then maintained carcinogen-free for 28 and 8 wk, respectively. Rats were treated with 30 mg/kg DMN ip; 4.5 hr later, chilled Eagle's minimal essential medium was perfused through the portal vein. DNA synthesis was studied in excised livers that had been incubated with ³H-thymidine. Without prior DMN treatment, fairly large numbers of grains were localized on the cytoplasm and nuclei of both normal liver and hyperplastic nodules, probably due to incorporation of tritiated moieties from catabolized ³H-thymidine into macromolecules other than nuclear DNA. After DMN treatment, normal liver cells showed increased number of grains on the nuclei. The two hyperplastic nodules and one hepatoma examined showed no increase in ³H-thymidine incorporation into nuclei after DMN treatment, whereas surrounding liver showed a distinct increase of grains on the nuclei, as did normal liver cells. These results show that *in vivo* DMN treatment decreases unscheduled DNA synthesis in hyperplastic nodules and hepatomas, suggesting that these lesions may be capable of escaping from carcinogen-induced DNA damage *in vivo*. - 78-6746 Deuterium Isotope Effect on Rat Liver DNA Damage In Vivo by Dimethylnitrosamine.** (Eng) Oshiro, Y. (Searle Labs., Box 5110, Chicago, IL, 60680); Sarma, D. S.; Zielinski, W. L. *Chem Biol Interact* 23(2): 263-266; 1978.

The deuterated analog (DMN-d₆) of dimethylnitrosamine (DMN) proved to be less effective than DMN in inducing *in vivo* DNA damage after ip administration to rats in doses from 0.37 to 3.20 mg/kg. Hepatic cell DNA damage after labeling with ³H-thymidine was measured by alkaline sucrose gradient sedimentation. At all dose levels, DMN-d₆ treatment resulted in a greater percentage of labeled DNA sedimenting at a mol wt > 13 x 10⁶ than DMN treatment. The distribution of slower-sedimenting DNA was always lower after DMN-d₆ than after DMN treatment. The sedimentation as heavy DNA, compared with control DNA, was taken to be a direct indication of DNA damage. The differences in the ability of DMN-d₆ and DMN to cause *in vivo* DNA damage were apparent at 10 min after administration, but they became less apparent with longer periods between treatment and sacrifice. Because DMN has to be metabolized to chemically modify DNA, it is hypothesized that the differential mutagenic capability of DMN-d₆ is due to the slower activation of this perdeuterated analog. - 78-6748 The Significance of Some Modifying Factors During Transplacental Blastomogenesis by Ethylnitrosourea in Rabbits.** (Eng) Dimant, I. N. (Uzbek Res. Inst. Oncology and Radiology, 700 000 Tashkent USSR); Beniashvili, D. Sh. *Neoplasma* 25(4): 453-460; 1978.

The effects of three treatments, organospecific immunity, chronic irritation of the peripheral nerve, and methylnitrosourea (MNU), on the development of ethylnitrosourea (ENU)-induced transplacental blastomogenesis were studied in chinchilla rabbits. Groups of 36 weaned rabbits, whose mothers had been treated during pregnancy with ENU, either served as controls or underwent one of the three treatments. The immunized animals (Group 1) were treated three times with antigens from the homologous tissue of the sciatic nerve

Group 2, the left sciatic nerve was chronically irritated by applying a nylon squeezing free ligature, the ends of which were attached to the femoral muscle. Contraction of this muscle produced irritation of the nerve. The MNU-treated animals (Group 3) received a weekly iv dose of 10 mg/kg for 5 mo. All animals were observed for 4 yr. The total number of tumors developing in survivors, 27 Group 1, 26 Group 2, 10 Group 3, and 36 control rabbits, was 17, 12, 4, and 10, respectively. The total number of peripheral nervous system tumors in the respective groups was 8, 7, 2, and 4. It appears that the first two treatments increased the frequency of tumor development, particularly that of peripheral nerve tumors. MNU apparently inhibited ENU-induced tumorigenesis. (25 refs)

78-6749 Studies of Experimental Brain Tumorigenesis Induced by Transplacental Administration of Diethylnitrosourea in Rats. (Jpn) Inui, S. (Second Dept. Surgery, Nara Medical Univ., Nara, Japan). *J Nara Med Assoc* 9(1): 288-306; 1978.

Wistar rats were given a single transplacental dose of ethylnitrosourea (ENU: 10-75 mg/kg), 4-hydroxyaminoquinoline N-oxide (4-HAQO: 7 mg/kg), or N-bis(2-hydroxypropyl)nitrosamine (DHPN: 2,000 mg/kg) on gestation days 18 or 20, and DNA synthesis and histopathological changes in the fetal brain were analyzed. Four hours after administration on day 18, ENU, 4-HAQO, and DHPN inhibited DNA synthesis by 87.7%, 85.6%, and 87.3%, respectively, with the inhibition due to ENU being dose-dependent. In ENU- and 4-HAQO-treated rats, the inhibition persisted for 48 hr, followed by a stimulation of synthesis at 72 hr after administration. Brain tumors were induced by ENU but not by 4-HAQO and DHPN. The incidence in males and females ranged from 36.4% to 66.7% at 23 wk and from 90.3% to 100% at 30 wk. In order of incidence, the tumors were oligodendrogliomas, astrocytomas, mixed gliomas, anaplastic gliomas, medulloblastomas, and trigeminal neurinomas. Atypical cell foci were observed as early as 10 wk, and the incidence of these foci was higher than that of the tumors at 23 wk and lower at 30 wk. The labeling index of the oligodendrogliomas, astrocytomas, anaplastic gliomas, neurinomas, and atypical cell foci was 1.92, 3.16, 7.52, 3.49, and 0.075, respectively. The atypical cell foci may represent preneoplastic lesions. (41 refs)

78-6750 Influence of Repeated Liver Regeneration on Hepatic Carcinogenesis by Diethylnitrosamine in Mice. (Eng) Pound, A. W. (Dept. Pathology, Univ. Queensland, Brisbane, Australia); McGuire, L. J. *Br J Cancer* 37(4): 595-602; 1978.

The effect of repeated doses of CCl₄ ip at 5-wk intervals on the tumorigenic response of diethylnitrosamine (DEN)-treated random-bred male Quackenbush mice was determined.

The mice were divided into six groups: 1 (a), 0.25 ml/kg CCl₄ ip; (b), 24 hr later, 80 mg/kg DEN ip and, 5 wk later, repeated doses of CCl₄; 2, regimen 1b; 3, regimen 1a + DEN; 4, DEN; 5, repeated CCl₄; 6, regimen 1a. No tumors were noted in mice given single or multiple injections of CCl₄. DEN + repeated CCl₄ injections increased the tumor yield in the liver over that occurring in animals treated with DEN alone. A single hepatonecrotic dose of CCl₄ 24 hr before DEN treatment also increased the number of tumors produced. The effects of the pre-DEN CCl₄ dose and the post-DEN CCl₄ doses were additive and were therefore independent of each other. The neoplasms produced were hepatocellular tumors and cholangiomas. Kidney tumors (papillary adenomas and adenocarcinomas) were also noted in the CCl₄ + DEN-treated mice. These findings indicate that the liver in the regenerative phase after a hepatonecrotic CCl₄ dose is more susceptible than normal liver to the initiating action of DEN and that repeated doses of CCl₄ after DEN provide a promoting stimulus. (18 refs)

78-6751 Effects of the Carcinogen, N-Methyl-N'-Nitro-N-Nitroguanidine (MNNG), on Differentiation of Human Prostate Epithelium in Organ Culture (Meeting Abstract). (Eng) Sanefuji, H. (Dept. 78-6753 Mycosis Fungoides, Nitrogen Mustard and Skin Cancer. (Eng) Du Vivier, A. (St. Mary's Hosp., London W2, England); Vonderheid, E. C.; Van Scott, E. J.; Urbach, F. *Br J Dermatol* 99(1): 61-63; 1978.

The development of epithelial malignancies prior to or after treatment with topically applied nitrogen mustard (mechlorethamine, HN₂) was determined in 202 patients (135 men, 67 women) with mycosis fungoides and its Sezary variant. The records of the patients, who had been followed for up to 9 yr, were reviewed. Epithelial cancers developed in 24 patients, 3 of whom were excluded from further study because of previous treatment with arsenic. The remaining 21 patients (12 men, 9 women) had a mean age at onset of lesions of 64 yr. The mean time between initiation of HN₂ therapy and detection of epithelial neoplasms other than actinic keratoses was 4.0 yr. Of eight patients who had lesions removed prior to HN₂ therapy (Group I), five developed additional lesions after HN₂ treatment [4 squamous cell carcinomas (SCC), 4

keratoacanthomas, and 1 basal cell carcinoma]. Three of these patients had multiple tumors. The other 13 patients (Group II), who had no evidence of epithelial lesions initially, subsequently developed actinic keratoses (4 patients) and 7 SCC, 3 keratoacanthomas, and 2 basal cell carcinomas (9 patients, 3 of whom developed multiple tumors). Two of the SCC were found in locations protected from solar radiation, which offers convincing evidence that topically applied HN₂ is a carcinogen or cocarcinogen. These lesions, which appeared 6-7 yr after the start of treatment, corresponded to the use of approx 14 g HN₂/4 yr (SCC on scrotum) and 16 g/7 yr (SCC on buttock). (7 refs.)

78-6754 In Vivo Synthesis of 1-Naphthyl N-Methylnitrosocarbamate (Nitrosocarbaryl) in the Rat and Guinea Pig (Meeting Abstract). (Eng) Rickard, R. W. (Graduate Center Toxicology, Univ. Kentucky, Lexington, KY, 40506); Dorrough, H. W. *Pharmacologist* 20(3): 146; 1978. (no refs)

78-6755 Inhibition of the Alkylation of Nucleic Acids and of the Metabolism of 1,2-Dimethylhydrazine by Aminoacetonitrile. (Eng) Pegg, A. E. (Dept. Physiology, Milton S. Hershey Medical Center, Pennsylvania State Univ., Hershey, PA, 17033). *Chem Biol Interact* 23(2): 273-279; 1978.

Administration of aminoacetonitrile (AAN) ip to female Sprague-Dawley rats before ip injection of ¹⁴C-1,2-dimethylhydrazine (DMH) altered the latter's metabolism to ¹⁴CO₂ and ¹⁴C-azomethane. The amount of ¹⁴CO₂ expired by treated rats was determined by drawing air through their cages, collecting it in gas-filled wash bottles, and measuring the radioactivity present in the bottles. When 100 mg/kg AAN was administered before 2 mg/kg ¹⁴C-DMH, CO₂ production 8 hr later was reduced from 28% to 4%, and azomethane increased from 1.3% to approx 50% of the administered DMH dose. Results were similar when the ¹⁴C-DMH dose was reduced to 0.5 mg/kg. When ¹⁴C-DMH dose was increased to 50 or 200 mg/kg, azomethane expiration rose to 33% and 41% of the administered dose, respectively, and ¹⁴CO₂ exhalation dropped to 11% and 6%. Alkylation of rat DNA at the 7-methylguanine position after administration of 2 mg/kg DMH was inhibited 95% in the liver, 89% in kidney, and 57% in colon by pretreatment with 100 mg/kg AAN. O⁶-methylguanine production was inhibited to a similar extent. The difference in the degree of inhibition of colon DNA suggests that at least one critical step in the conversion of DMH to a methylating agent for the colon occurs outside the liver. (26 refs)

78-6758 Long-Term Effects of Phenobarbitone-Na Male Fischer Rats. (Eng) Butler, W. H. (Safety Medicines Dept., Pharmaceuticals Div., ICI, Ltd., Mereside, Alderley Park, Macclesfield, Cheshire, SK10 4TG, England). *Br J Cancer* 37(3): 418-423; 1978.

Preliminary results are given of an experiment in which male inbred Fischer rats were fed sodium phenobarbitone at a level of 500 ppm in the diet for 1 wk followed by 1,000 ppm for 103 wk. Of 33 rats surviving ≥ 80 wk, 11 had small foci of nodular hyperplasia; however, 1 killed at 102 wk had a larger lesion (0.75 cm) with no evidence of local invasion or metastases. All livers had evidence of parenchymal cell damage. No nodular hyperplasia was found in the controls. It is concluded that this compound is not carcinogenic in Fischer rats. (9 refs)

78-6761 Relative Sensitivities of Forward and Reverse Mutation Assays in *Salmonella typhimurium*. (Eng) Skopek, T. R. (Toxicology Group, Dept. Nutrition and Food Science, Massachusetts Inst. Technology, Cambridge, MA, 02139); Liber, H. L.; Kaden, D. A.; Thilly, W. G. *Proc Natl Acad Sci USA* 75(9): 4465-4469; 1978.

The relative sensitivities of the forward and reverse mutation assays in *Salmonella typhimurium* were compared with the

of 16 mutagens of both base-substitution and frameshift types. Forward mutation of 8-azaguanine resistance was measured with strains TM35 and TM677; reverse mutation of histidine prototrophy was measured with the Ames tester strains TA1535, TA1537, TA1538, TA98, and TA100. The spontaneous revertant mutant fractions ranged from 1×10^{-8} (TA1538) to 22×10^{-8} (TA100). The mean spontaneous forward mutant fraction was 1.7×10^{-5} for TM35 and 1×10^{-5} for TM677. The two approaches were found to be sensitive for all 16 mutagens; ie, induction of significant mutation occurred at similar concentrations in the forward mutation assay and in the most sensitive of the five Ames tester strains. The combined assays provide an improved means of quantitating chemomutagenic potential. (9 refs)

78-6762 **Mutagenic Properties of Quinoline.** (Eng) Hollstein, M. C. (Univ. California, Berkeley, CA). *Abstr Int B* 39(2): 673; 1978. (no refs)

78-6763 **Macroautoradiographic Assays of ^{14}C -Labeled 4-Nitroquinoline 1-Oxide in Adult and Fetal Liver.** (Eng) Takahashi, G. (Dept. Pathology, Chest Disease Res. Inst., Kyoto Univ., Kyoto, Japan); Kinoshita, K.; Uehira, K. *Bull Chest Dis Res Inst Kyoto Univ* 11(1/2): 90; 1978.

The distribution of ^{14}C -labeled 4-nitroquinoline 1-oxide (4NQO) and its metabolites in adult, pregnant, and fetal mice was studied by macroautoradiography. 4NQO (7.5 μCi , 230 μg) was administered iv to pregnant mice on days 16 or 19 of gestation or injected iv or sc in young adult mice. All animals were killed 1, 3, 5, or 24 hr later. Concentrations of radioactive substances were nearly equal in fetal tissue, placenta, and maternal blood 1 hr after iv administration. Although fetal organ distribution of radioactivity was uniform on day 16 of gestation, the 19 kidneys, urinary bladder, and intestinal tract were intensely labeled on day 19. In normal adult mice, radioactivity 1 hr after iv 4NQO administration was concentrated most intensely in the gallbladder, small intestine, lungs, kidneys, and bladder. There was moderate activity in the liver, heart, muscle, salivary glands, and blood. Radioactive substances tended to deposit at the injection site after sc administration, but they also accumulated in the gallbladder, intestine, bladder, and kidneys. No direct relationship between organ susceptibility to 4NQO and the concentration of radioactivity was observed. (10 refs)

78-6764 **Effect of a Single Injection of 4-Dimethylaminoazobenzene on Some Properties of Rat Liver Cell Mitochondria.** (Rus) Medvedeva, N. D. (Lab. Tumor Cytology, Inst. Cytology, Acad. Sciences, USSR, Leningrad, USSR); Khodosova, I. A. *Tsitologiya* 20(10): 1102-1106; 1978.

The effects of a single ip injection (250 mg/kg) of the hepatocarcinogen 4-dimethylaminoazobenzene (DAB) and its non-carcinogenic analog, 4-diethylaminoazobenzene (DEAB), on rat liver mitochondria were studied. DAB had no noticeable effect on mitochondrial and cytoplasmic malate dehydrogenase activity. Both substances caused a significant inhibition of mitochondrial cytochrome oxidase activity on the first day (to 51.3% by DAB and to 42.2% by DEAB), but there was no significant difference between the effects of the two substances. This activity returned to normal levels on day 4. The swelling-contraction properties of isolated mitochondria were reduced in the presence of succinate and ATP, even 18 days after a single DAB injection. However, DAB had no effect on mitochondria from the kidney, which is not its target organ. The changes are interpreted as the result of the action of the carcinogen on the mitochondrial membranes. 78-6765 **Need for Ascertaining Environmental History in Leukemia and Malformations in Children.** (Swe) Haglund, B. (Halsovardsenheten, Bassjukhuset, S-541 00 Skovde, Sweden); Kjellman, B. *Lakartidningen* 75(39): 3436-3437; 1978.

The necessity and importance of ascertaining the environmental history of children with leukemia and malformations are illustrated by case reports. A woman exposed occupationally to xylene vapors and freon in an unventilated room gave birth to a boy who was subsequently exposed to styrene, acetone, and xylene while his father was building a plastic boat. The boy developed acute lymphocytic leukemia at age 2 yr. One of the mother's colleagues gave birth to a girl with bilateral talipes equinovarus, the other to a girl with gastroschisis and exstrophy of the bladder. A 10-yr-old boy developed acute leukemia a few months after he was exposed to solvents, mainly trichloroethylene, while building plastic models. A 6-yr-old girl exposed frequently to solvents and living in a house in which the radioactivity level was about four times higher than the background level developed leukemia. The girl's grandfather, who had been occupationally exposed to solvents as an automobile mechanic, died from chronic lymphocytic leukemia. (13 refs)

78-6766 **A Study of Cyclic Nucleotide Metabolism and the Histology of Rat Liver During 3'-Methyl-4-dimethylaminoazobenzene Carcinogenesis. II. Cyclic AMP Metabolism.** (Eng) Boyd, H. (Dept. Pharmacology, Univ. Miami Sch. Medicine, P. O. Box 520875, Miami, FL, 33152); McAfee, D. A.; Rubin, J. J. *Tissue Cell* 10(3): 477-494; 1978.

Adenyl cyclase (AC) activity and cyclic AMP (cAMP) metabolism were studied in Sprague-Dawley rat livers undergoing carcinogenesis induced by dietary 3'-methyl-4-dimethylaminoazobenzene (0.06%). All treated rats developed

cholangiocarcinomas by 10 wk. AC activity, assessed from the crude membrane fraction, increased slowly for 3 wk and then rose to a peak of 565% of control values at 9 wk post-treatment. Stimulation with isoproterenol increased this peak to 640%; guanylimidodiphosphate (Gpp(NH)p) and sodium fluoride also stimulated AC activity, but glucagon had no significant effect. Enzyme activity was higher in tumor-bearing animals than in controls, and it was higher in areas of tumor involvement than in noninvolved tissue from the same animal. The patterns of responsiveness to the AC stimulators indicated that there were differences not only in the onset of hormonal stimulation of the enzyme and the transduction mechanism, but also a difference in the time at which these changes were no longer seen. The former preceded tumor induction; the latter accompanied tumor induction and persisted in tumors and uninvolved tissue. Cyclic AMP levels in treated animals showed a consistent and significant elevation (120%-250%) after wk 3, but they were strikingly increased in tumor tissue (up to 1500%). Particulate phosphodiesterase activities increased in the first 2 wk after treatment, then declined in tumor-bearing livers to levels similar to those in non-tumor-bearing livers. (64 refs)

- 78-6767 A Study of Cyclic Nucleotide Metabolism and the Histology of Rat Liver During 3'-Methyl-4-dimethylaminoazobenzene Carcinogenesis. III. Cyclic GMP Metabolism.** (Eng) Boyd, H. (Dept. Pharmacology, Univ. Miami Sch. Medicine, P.O. Box 520875, Miami, FL, 33152); McAfee, D. A.; Laumen, G.; Rubin, J. J. *Tissue Cell* 10(3): 495-504; 1978.

Cyclic guanosine monophosphate (cGMP) metabolism and guanylate cyclase (GC) activity were studied during the development of liver cholangiocarcinomas in Sprague-Dawley rats fed a diet containing 0.06% 3'-methyl-4-dimethylaminoazobenzene. Tumor incidence at 10 wk was 100%. Changes in GC activity were apparent in soluble (SF) and particulate fractions (PF), with and without added Triton X-100 (0.5%). PF activity without Triton increased slightly in the first 3 wk post-treatment, decreased to 50% of control values at 3-5 wk, and then increased to a sharp peak (300% of control values) at 10 wk. SF activity varied in a roughly inverse manner: it showed no appreciable changes for 3 wk, increased to 180% of control values during wk 3-5, then returned to normal before increasing to a sharp peak at wk 10. This peak correlated with the peak tumor incidence. The activity of SF- and Triton-activated PF enzyme increased in tumor-bearing animals, but even more so in tumor tissues. Cyclic GMP levels in uninvolved tissue dropped to 30%-40% of control values during the first 2 wk, but they increased at 4 wk and reached 160% of control values by 10 wk. SF cyclic GMP-phosphodiesterase was consistently elevated (150% of control values) in treated animals after 1 wk, as were PF activities at 1 μ M substrate. Higher substrate concentrations, decreased PF enzyme activity. The ratio of cGMP/cAMP decreased in the following order: < in tumors < uninvolved tissue < controls. (33 refs)

- 78-6768 Work-related Origin of Cancer in the Nose, Mouth, Throat, and Larynx.** (Ger) Kup, H. (Sitzungsberichte der Akademie der Wissenschaften und der Literatur, Berlin, E. Germany). *Akademie der Wissenschaften* 2(2): 20-25; 1978.

The rarity of cancer of the ear, nose, and throat in relation to the total cancer morbidity makes it difficult to single out work-related causes. Among a series of 15 patients seen by the author, there were 12 cases of laryngeal carcinoma, 2 cases of epipharyngeal cancer, and 1 case of nasal carcinoma. Only three of these patients were nonsmokers. The only possible association with occupation could be made by six laryngeal carcinoma patients: four had occupational exposure to naphthalene, and two worked in the tire manufacturing industry. It is suggested that most of these cancers result from non-work-related causes. (11 refs)

- 78-6769 Pathways of DNA Repair Operating in Yeast Cells Treated with the Pyrrolo(1,4)benzodiazepine Antitumor Antibiotics.** (Eng) Hannan, M. A. (Div. Medicinal Chemistry and Pharmacognosy, Coll. Pharmacy, Univ. Kentucky, Lexington, KY, 40506); Hurley, L. H. *J Antibiot (Tokyo)* 31(9): 911-913; 1978.

Two principal pathways for the repair of potentially mutagenic lesions produced by anthramycin, sibiromycin and tomaymycin in *Saccharomyces cerevisiae* were identified. These pathways utilize the *RAD 1* gene product concerned with the excision of UV-induced dimers and the *RAD 52* gene product concerned with the repair of ionizing radiation-induced DNA strand breaks. - 78-6772 The Formation of Dihydrodiols by the Chemical or Enzymic Oxidation of Benz(a)anthracene**

7,12-Dimethylbenz(a)anthracene. (Eng) Tierney, B. (Cancer Res. Inst., Inst. Cancer Res., Royal Cancer Hosp., Fulham Road, London SW3 6JB, England); Hewer, A. D.; MacNicoll, A. D.; Giovanni Gervasi, P.; Rattle, H.; Grover, P. L.; Sims, P. *Chem Biol Interact* 23(2): 257; 1978.

A quick simple method of obtaining small amounts of trans-dihydrodiols (trans-DHD) from benz(a)anthracene (BA) and 7,12-dimethylbenz(a)anthracene (DMBA) is described. The characterized trans-DHD of these hydrocarbons were used as reference compounds in the high-pressure liquid chromatography (HPLC) analysis of DHD mixtures formed by the metabolism of the parent hydrocarbons by rat liver microsomal preparations, and the formation of several previously unreported metabolic non-K-region trans-DHD was detected. The non-K-region DHD trans-1,2-dihydro-1,2-dihydroxy-BA and trans-3,4-dihydro-3,4-dihydroxy-BA together with small amounts of the trans-8,9- and trans-10,11-DHD, were formed when BA was oxidized in a reaction mixture containing ascorbic acid, ferrous sulfate, and EDTA. When oxidized in a similar system, DMBA yielded the K-region DHD trans-5,6-dihydro-5,6-dihydroxy-DMBA and the non-K-region DHD trans-1,2-dihydro-1,2-dihydroxy-DMBA, trans-3,4-dihydro-3,4-dihydroxy-DMBA, trans-8,9-dihydro-8,9-dihydroxy-DMBA, trans-10,11-dihydro-10,11-dihydroxy-DMBA, and a trace of the 1,2-DHD. The structures and stereochemistry of the DHD were established by comparisons of their UV spectra and HPLC characteristics with those of authentic compounds or, when no authentic compounds were available, by UV, nuclear magnetic resonance, and mass spectral analysis. The metabolic DHD were identified by comparisons of their chromatographic and fluorescence spectral characteristics with compounds of known structures. The principal metabolic DHD formed from BA and DMBA were the trans-5,6- and trans-8,9-DHD. The 1,2- and 10,11-DHD were identified as minor products of the metabolism of BA, and tentative identification of the trans-3,4-DHD as a metabolite was made from fluorescence and chromatographic data. The minor metabolic DHD formed from DMBA were the trans-3,4-DHD and the trans-10,11-DHD, but the trans-1,2-DHD was not detected. (23 refs)

78-6773 Biochemical Studies on Cultured Epithelium-like Cells. (Eng) Weisburger, E. K. (Carcinogen Metabolism and Toxicology Branch, NCI, Bethesda, MD, 20895); Idoine, J.; Elliot, J. M. In: *Rat Liver Neoplasia; Workshop on Rat Liver Neoplasia held by William F. Merrell, Co. Woods Hole, October, 1974*. William F. Merrell, Co. Woods Hole, MA: 288 pp.; 220-227; 1978.

Spontaneous transformation and aryl hydrocarbon hydroxylase (AHH) activity were monitored in eight epithelial cell lines derived from the livers of 7- to 10-day-old Fischer rats. In an initial assay, the specific AHH activity was 8.3-13.4 units/mg protein/min incubation at 37 C. Of four lines kept

in continuous culture, the AHH activity of one was high at the end of 6 mo, the activity of another showed only trace levels, and the activities of the other two remained constant. No tumors developed in animals inoculated with cells from two of the four lines, whereas one animal each developed a tumor (out of each experimental group of 8 rats) following inoculation with cells from the other two lines. AHH activity increased following treatment of cultures with benz(a)anthracene, 7,12-dimethylbenz(a)anthracene, 3-methylcholanthrene, and, to a lesser extent, with phenobarbital. The data indicate that there are biochemical differences in epithelial cell lines derived from the same host tissue and that the level of AHH activity cannot be used as a criterion for the transformed or normal status of cells in culture. 78-6774 Development and Characterization of Mammary Tumors and Mammary Dysplasias Induced with 7,12-Dimethylbenz(a)anthracene in Lewis Rats. (Eng) Haslam, S. N. (Univ. California, Berkeley, Berkeley, CA). *Diss Abstr Int B* 39(2): 503; 1978. (no refs)

78-6775 Induced Cancer of the Mammary Gland in Rats. (Rus) Kisliakova, N. D. (Hormonal Lab., Res. Inst. Oncology, Rostov-on-Don, USSR); Verevkina, G. A.; Ogorodnikova, L. S.; Kucherova, T. I. *Vopr Onkol* 24(8): 93-97; 1978.

A new method for the mass induction of experimental cancer of the mammary gland in rats is described. To stimulate proliferation in the mammary gland epithelium, random-bred albino rats were fed fresh human placenta (5-6 g/day), which contains large amounts of estrogens and progesterone, for 1.5 mo. One week after the start of this treatment, the animals received dimethylbenz(a)anthracene (DMBA: 10 mg, intragastrically). Ten days later rats received a second dose of DMBA and, 1 mo later, a third dose. Mammary gland tumors were induced in 22/26 rats (1 rat developed a uterine tumor). Tumors were first detected within 1.5 mo of administration of the last DMBA dose. Histologically, the tumors were similar to glandular human breast carcinoma. (7 refs)

78-6776 Developmental Stage of the Rat Mammary Gland as Determinant of its Susceptibility to 7,12-Dimethylbenz(a)anthracene. (Eng) Russo, I. H. (Experimental Pathology Lab., Dept. Biology, Michigan Cancer Foundation, 110 E. Warren Ave., Detroit, MI, 48201); Russo, J. *J Natl Cancer Inst* 61(6): 1439-1449; 1978.

Mammary gland development was compared in 80 normal Sprague-Dawley (SP) virgin rats, aged 2-112 days, and 60 SD virgin rats that, at age 55 days, were treated with 7,12-dimethylbenz(a)anthracene (DMBA: 10 mg/100 g intragastrically). Animals of both groups were killed weekly and their

mammary glands were examined in whole-mount preparations. During the first wk of postnatal life, the rat mammary gland was composed of a single lactiferous duct with 3-5 secondary branches termed terminal end-buds (TEB). The TEB grew in size and number for 21 days, then differentiated mainly into alveolar buds (AB). The AB increased steadily until age 70-84 days and differentiated into lobules with the onset of the estrous cycle at 35-42 days. Beginning at age 14 days, undifferentiated TEB's decreased in size and diameter to become terminal ducts (TD), a process that persisted until age 84 days. Therefore, in 84-day-old animals, most TEB's had differentiated into AB or TD. DMBA was administered to the rats at a time when differentiation into AB should have been rapidly progressing and TEB's decreasing. However, the number of TEB's remained constant or decreased only slightly from 5.4 to 4.6 TEB/mm². Between days 14 and 21, TEB's began increasing markedly in size (103.0 to 226.3 μ) and were termed intraductal proliferations (IDP). Mitotic activity was high in IDP's, which evolved into microtumors (400 to 750 μ) with the characteristics of adenocarcinoma. In the DMBA-treated animals, decreases in AB and lobules were correlated inversely with the increase in TEB and TD. Although these types of differentiations have not been proven conclusively in humans, there is evidence for an analogous mechanism in the development of human breast carcinoma. (32 refs)

78-6778 Alteration of Pituitary Hormone Secretion in Rats During the Induction of Mammary Tumors by Dimethylbenzanthracene. (Fre) El Abed, A. (Laboratoire des Hormones polypeptidiques, C.N.R.S., 91190 Gif-sur-Yvette, France); Valens, M.; Langlois, Y.; Kerdellhue, B. *C R Acad Sci [D]* (Paris) 285(16): 1483-1486; 1977.

The secretion of pituitary hormones in various phases of the estrous cycle was studied in female Sprague-Dawley rats during the induction of mammary tumors by 9,10-dimethyl-1,2-benzanthracene (DMBA). Palpable mammary tumors usually appeared in the rats during the 14th cycle after the administration of 15 mg DMBA by gastric tube. Serum concentrations of luteinizing hormone (LH), follicle-stimulating hormone (FSH), prolactin (PRL), thyroid-stimulating hormone (TSH), and gonadotrophic hormone (GH) were measured on the morning and afternoon of the proestrus and estrus phases of the 2nd-14th cycles after drug administration. An immediate effect of the carcinogen was a decrease in the preovulation peaks of LH and FSH, observed in the afternoon of proestrus; at the same time, concentrations of PRL remained elevated. Concentrations of GH and TSH

were usually lower in the DMBA-treated rats. Apparent pituitary hormone secretion is altered in rats susceptible to mammary tumor formation by DMBA. (17 refs)

78-6779 Role of Pineal Gland in Aetiology and Treatment of Breast Cancer (Letter to Editor). (Er) Tapp, E. (Group Lab., Preston Royal Infirmary, Preston Lancashire, England). *Lancet* 2(8097): 1001-1002; 1978.

Hypersecretion of the pineal gland may be implicated in the etiology of breast cancer. Melatonin increases the secretion of prolactin, a substance implicated in the development of breast cancer. Dimethylbenzanthracene-induced mammary tumors in rats show increased malignancy if melatonin secretion is given. Moreover, suppression of the pineal gland under conditions of continuous daylight reduced the incidence and degree of malignancy of breast tumors. (5 refs)

78-6780 Morphological Changes in the Development of 7,12-Dimethylbenz(a)anthracene-induced Mammary Tumors. (Jpn) Kobuchi, K. (Dept. Surgery, Okayama Univ. Medical Sch., Shikata-cho, Okayama 700 Japan). *Okayama Igakkai Zasshi* 90(3/4): 313-334; 1978.

7,12-Dimethylbenz(a)anthracene (DMBA: 20 mg) was administered by gastric intubation to 55-day-old Sprague-Dawley rats, and morphological changes occurring during mammary gland carcinogenesis were followed. Rats (2-3) were sacrificed daily during the first week after DMBA administration, and then weekly up to 20 wk. At each stage, mammary glands were examined by the whole-mount method, optical microscopy, and electron microscopy. On day 4 after DMBA administration, mammary epithelial cells at the peripheral portion of the duct showed dilatation of the endoplasmic reticulum and Golgi apparatus. By 2 wk, hypersecretion was well-established. At 4 wk, the epithelial cells were atrophied and their intracellular organelles were regressed. However, myoepithelial cells displayed cytoplasmic extensions that surrounded mammary epithelial cells. The stroma around the ductules showed marked proliferation. At 7 wk, hyperplastic alveolar nodules were found. Among some rat stroma growing around the ductules became fibroadenomatous. At 9 wk, tumors (tubular adenocarcinomas) were palpable. Electron microscopy of the carcinoma demonstrated an increased nucleocytoplasmic ratio, nuclear irregularities, hypertrophy of the nuclear membrane, and enlargement of the intracellular space. (31 refs)

78-6781 Measurement of Aryl Hydrocarbon Hydroxylase and NADH-dependent Cytochrome c Reductase Activities in Mitogen-activated Human Lymphocytes. (Eng) Kouri, R. E. (Dept. Biochemical Oncology, Microbiological Associates, Bethesda, MD, 20014); Imblum

L.; Prough, R. A. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for Detection and Prevention of Cancer. (New York, NY): 1978. 2(part 1), 2404 pp.; 1659-1676; 1978.

Factors that influence mitogen activation and induction of hydrocarbon hydroxylase (AHH) activity in cultured human lymphocytes were examined. The most effective mitogens for lymphocyte activation were phytohemagglutinin (PHA), PHA plus pokeweed mitogen, leucoagglutinin. The AHH activity of cultured human lymphocytes was influenced by factors such as type and lot of fetal calf serum, type and concentration of mitogen, kind of inducer, initial cell concentration, and degree of mitogen activation. The degree of 3-methylcholanthrene (3-MC)-induced (and noninduced) AHH activity paralleled the degree of mitogen activation. At concentration of 2-5 μ M, benz(a)anthracene and 5,6-benzoflavone efficiently induced AHH activity to levels similar to that induced by 3-MC. Presentation of AHH activity based on level of cytochrome *c* reductase activity rather than on the number of cells or total DNA resulted in consistently lower interassay variation. Two other factors that helped yield a lower interassay variation were the use of lot No. 88973 fetal calf serum, which resulted in basal AHH levels 5-15 times above zero time fluorescence values, and the use of an initial cell concentration of 1.5×10^6 cells/ml, which routinely resulted in peak AHH activity for both 3-MC-induced and control cultures at 72 hr. (42 refs)

6782 **Induction of Tumor-Cytostatic Macrophages by Phorbol-12,13-Diester (Meeting Abstract).** (Eng) Grimm, W. (Institut f. Immunologie der Universitat, Heidelberg, W. Germany); Gerns, D. *Z Immunitaetsforsch* 5(1): 19; 1978. (no refs)

6783 **Electrochemical Investigations on Several Dimethylbenzo(a)pyrenes.** (Eng) Park, S. M. (Dept. Chemistry, Univ. New Mexico, Albuquerque, NM, 87131); Michnovicz, J. J.; Daub, G. H. *Anal Biochem* 90(1): 4-388; 1978.

Electrochemical studies were made of five dimethylbenzo(a)pyrene (DMBP) derivatives, 1,3-, 1,6-, 2,3-, 3,6-, and 5-DMBP, all of which have stronger carcinogenicity than benzo(a)pyrene (BP). A three-electrode cell housing a platinum disk working electrode, a Pt wire auxiliary electrode,

and a silver wire pseudoreference electrode were used to record the cyclic voltammetry and chronopotentiometry in (1:1) acetonitrile-benzene solns with tetra-n-butylammonium perchlorate as a supporting electrolyte. The oxidation and reduction of DMBP's were demonstrated to be reversible one-electron processes, forming the cation and anion radicals, respectively, as the electrode reaction products. Cyclic voltammograms indicated that the cation radicals are very stable. The half-lives calculated from pseudo-first-order decay rate constants were estimated to be 150, 11.4, and 7.7 sec for the 1,3-, 2,3-, and 3,6-DMBP's, respectively. The one-electron electrooxidations may be due to the stabilization of the cation radicals by methyl substituents and to the dryness of the solvent. The cation radicals of the DMBP's were more stable than those of benzo(a)pyrene (previous study). Studies of reactions of cation radicals with nucleophiles such as water and pyridine showed that blocking at the 6-position lowered the reactivity of the cation radical toward water, a mild nucleophile. Pyridine was too strong to be affected by 6-position blocking. (27 refs)

78-6784 **Benzo(a)Pyrene 7,8-Dihydrodiol-9,10-oxide Modification of DNA: Relation to Chromatin Structure and Reconstitution.** (Eng) Yamasaki, H. (Dept. Medicine, Columbia Univ. Coll. Physicians and Surgeons, 701 W. 168th St., New York, NY, 10032); Roush, T. W.; Weinstein, I. B. *Chem Biol Interact* 23(2): 201-213; 1978.

DNA was modified by in vitro reaction with the 7,8-dihydrodiol-9,10-oxide of benzo(a)pyrene (BPDE), and the effects of this modification on the in vitro reconstitution of nucleosome structures were examined. In addition, intact chromatin (CT) was reacted with BPDE, and the distribution of the covalently bound BP residues was studied. Purified duck reticulocyte DNA modified by incubation with BPDE was more susceptible to partial digestion by the single-strand-specific endonuclease *S*₁ than unmodified DNA, suggesting slight denaturation of the helix at sites of modification. CT that was reconstituted using this carcinogen-modified DNA and unmodified CT-associated proteins showed the same kinetics and extent of digestion by *Staphylococcal* nuclease and similar nucleosome profiles on sucrose density gradient centrifugation as those obtained with native CT or CT reconstituted with unmodified DNA. Polyacrylamide gel electrophoresis of DNA fragments obtained from nuclease digests of the reconstituted CT's suggested that the CT containing carcinogen-modified DNA had the same subnucleosome structure as that reconstituted with unmodified DNA. After intact duck reticulocyte CT was reacted directly with BPDE, nuclease digestion studies indicated that 65% of the carcinogen was bound to the 'open' regions of CT and 35% to 'closed' regions (ie, regions highly susceptible to digestion by *Staphylococcal* nuclease vs regions relatively resistant to digestion). The results indicate that although covalent binding of a BP derivative to DNA produces local

distortions in conformation of the helix, this modification does not appear to interfere with the ability of the DNA to associate with histones to form nucleosome structures. Although DNA in the open regions of CT is more susceptible to reaction with the BP derivative, there is appreciable reaction with the DNA associated with histones. (46 refs)

- 78-6786 Pathologic Changes Induced in Respiratory Tract Mucosa by Polycyclic Hydrocarbons of Differing Carcinogenic Activity.** (Eng) Topping, D. C. (Natl. Inst. Environmental Health Sciences, Research Triangle Park, Durham, NC, 27709); Pal, B. C.; Martin, D. H.; Nelson, F. R.; Nettesheim, P. *Am J Pathol* 93(2): 311-324; 1978.

The toxic effects of benzo(e)pyrene (BeP), pyrene, anthracene, benz(a)anthracene (BA), dibenz(a,c)anthracene (DBA), benzo(a)pyrene (BP), and dimethylbenz(a)anthracene (DMBA) were investigated in the respiratory mucosa of male Fischer F-344 rats. These compounds were chosen because they comprise a spectrum of polycyclic hydrocarbons (PCH) ranging from noncarcinogens to initiators, weak carcinogens, and strong carcinogens. Heterotopic tracheal grafts were maintained under the dorsal skin of syngeneic recipients. The grafts were exposed to the test substance from an intraluminal beeswax pellet, which released the material slowly over 8 wk. The histopathologic effects were periodically assessed semiquantitatively. All PCH exhibited varying degrees of toxicity for the respiratory epithelium and submucosa. BeP showed the least toxicity, followed by pyrene and anthracene. BA and DBA caused marked epithelial and submucosal changes: epithelial hyperplasia, undifferentiated epithelium, and squamous metaplasia and marked mononuclear infiltration in the subepithelial connective tissue. With BP, the epithelial and submucosal changes were similar but stronger. DMBA was the most toxic substance, causing epithelial necrosis followed by generalized keratinizing squamous metaplasia; the subepithelial changes consisted of an early acellular exudate and, at 8 wk, marked condensation and hyalinization of the lamina propria. The toxic response pattern of the tracheal mucosa to carcinogens was characterized by the chronicity of epithelial and connective tissue damage, as opposed to the short-lived hyperplastic and inflamma-

tory response elicited by the noncarcinogens and initiators. (21 refs)

- 78-6787 Histochemical Patterns of a Few Key Carbohydrate Metabolic Enzymes During Hepatocarcinogenesis (Meeting Abstract).** (Ger) Hacker, H. J. (Hamburg, W. Germany); Bannasch, P. *Zentralbl Allg Pathol* 122(3): 289; 1978. (no refs)

- 78-6788 Inducibility of Aryl Hydrocarbon Hydroxylase in Cultured Human Lymphocytes.** (Eng) Fleischer, K. A. (Dept. Tropical Medicine, Univ. Liverpool, Box 147, Liverpool L69 3BX, England); Price Evans, D.; Canning, M. V. *J Med Genet* 15(3): 182-188; 1978.

The method for estimating aryl hydrocarbon hydroxylase (AHH) activity in cultured human lymphocytes was modified in an attempt to obtain reproducible values for AHH induction. However, none of the modifications produced the level of reproducibility required for quantitative genetic studies. (18 refs)

- 78-6789 Vaginal and Cervical Squamous Cell Dysplasia in Women Exposed to Diethylstilbestrol (DES) in Utero.** (Eng) Burke, L. (Beth Israel Hosp., 330 Brook Ave., Boston, MA, 02215); Antonioli, D.; Rosen, S. A. *Obstet Gynecol* 132(5): 537-544; 1978.

Pelvic, colposcopic, and histologic examinations were performed on 250 patients with a known or suspected history of in utero exposure to diethylstilbestrol (DES). (Exposure was confirmed in 205 cases.) Colposcopically abnormal areas were graded for severity according to predetermined criteria and biopsy evaluation was made for adenosis in vaginal squamous metaplasia, glandular or squamous metaplasia, nonglycogenated mucosa, and dysplasia in both vaginal and cervical specimens. No glandular or squamous carcinomas were noted, but a nonneoplastic abnormality was found in biopsy specimens of 82% of the women. Gross abnormalities included cervical columnar epithelium in 147 women and a cervicovaginal hood in 147. Adenosis was present in vaginal walls, fornices, and/or hood in 185 cases. Colposcopically abnormal areas were present in vaginas and hoods of 211 patients. Fifteen patients had squamous dysplasia, the degree of which was mild in 11 and moderate in 4 cases. The dysplasia involved the cervix in 14 patients and the vagina in 4. Patients with cervical mosaic and vaginal epithelium had dysplasia on biopsy much more frequently than patients with similar colposcopic appearances in the vagina. Thus, colposcopic data on cervical dysplasia can

applied to the evaluation of dysplasia in vaginal adenosis without modification. (16 refs)

78-6790 **Comparative Sensitivity of Animals of Various Species to the Carcinogenic Effect of Tryptophan Metabolites.** (Rus) Khrustalev, S. A. (Lab. Systemic Food Diseases, Cancer Res. Center, Moscow, USSR). *Patol Biol Eksp Ter* (4): 61-63; 1978.

The carcinogenic activity of tryptophan metabolites in guinea pigs, Syrian hamsters, and random-bred rats was compared. Animals of each species were divided into two groups: Group 1 was inoculated sc with 2-aminoacetophenone (2-AAP) and Group 2 was inoculated sc with 3-indolylacrylic acid (3-IAA) 2- to 3-day intervals. Both groups received inoculations for 5 mo; the total dose of each agent was 500-740 mg for guinea pigs, 200 mg for hamsters, and 200 mg for rats. The tumorigenic activity of 2-AAP and 3-IAA was most pronounced in the hamsters (there were 6 cases of lymphosarcoma, 2 cases of myeloid leukemia, 2 cases of lymphoid leukemia, and 1 case of plasmacytic leukemia of hemopoietic cells). Among the rats there were seven cases of lymphosarcoma, and among the guinea pigs there was one case of lymphoid leukemia. Both metabolites also induced various benign and malignant tumors in the hamsters (6 insulinomas of the pancreas, 1 adenoma of the pancreas, 2 liver cholangiomas, 1 papilloma of the vagina, 3 fibrosarcomas and fibromas, 1 melanoma, and 1 papillary carcinoma of the urinary bladder). Both metabolites also induced various tumors in rats (2 fibromas, 1 fibrosarcoma, 1 cystic epithelioma, 1 ovarian folliculoma, 1 uterine myxofibroma, 6 mammary and carcinomas). (7 refs)

78-6791 **Role of Hormones in Mammary Neoplasia.** (Eng) Nandi, S. (Dept. Zoology, Univ. California, Berkeley, CA, 94720). *Cancer Res* 38(11, part 2): 4046-4049; 1978.

A hypothesis for the role of hormones in mammary neoplasia as well as neoplasia in other endocrine organs and target tissues is presented. It is assumed that hormones are not carcinogenic by themselves but that they modify the host and/or target tissues during the events initiated by carcinogens such as viruses, chemicals, or radiation. The hypothesis is based on the observations that hormones are involved in regulating cell division in normal mammary cells, the emergence of overt mammary tumors requires hormonal stimulation of cells receiving a carcinogenic stimulus, normal cells have finite divisional life but neoplastic cells are immortal, and normal mammary cells might inhibit the growth of small numbers of preneoplastic and neoplastic cells. The hypothesis is that hormones have at least two functions in mammary carcinogenesis initiated by direct-acting carcinogens. First, hormones are necessary for DNA synthesis and mitosis of the initial transformed cells and, consequently, for their conver-

sion into fixed transformed cells with heritable characteristics. Second, hormones stimulate the rapid growth of normal cells with finite divisional life, leading to a reduction in their number in localized areas surrounding the transformed cells or in the tissue as a whole. This releases the transformed cells from the growth inhibitory influence of normal cells, allowing the emergence of overt tumors. (48 refs)

78-6794 **Dose-Effect Studies on Estrogen Induced Mammary Cancers in Mice.** (Eng) Rudali, G. (Equipe de Recherche 190 du C.N.R.S., Fondation Curie, 26, Rue d'Ulm, 75231 Paris, Cedex 05, France); Jullien, P.; Vives, C.; Apiou, F. *Biomedicine* 29(2): 45-46; 1978.

Castrated male (C3H x RIII)F1 mice were treated with graded doses of estradiol-17 β and estrone in a life-span experiment to determine to what extent the carcinogenic activity of estrogens in the mammary gland was dose-related. The mice were castrated at age 25 days; on the same day, paraffin pellets containing estradiol-17 β were implanted sc for continuous resorption. These pellets contained 1, 2.5, 5, 10, or 100 μ g of hormone. Other castrated mice received estrone po in the food at concentrations of 0.02, 0.2, or 2 ppm, corresponding to daily intakes of 0.06, 0.6 and 6 μ g, respectively. In addition, castrated females were ovariectomized and treated with the lower doses of the estrogens to see if they were sufficient to induce a vaginal estrus. Although the lower doses of both hormones induced vaginal estrus, they did not produce mammary tumors in the males. With the higher doses, however, the mammary tumor incidence was 95.8%-100%. These findings can be compared with clinical evidence in humans that continuous ingestion of low doses

of estrogens does not enhance breast cancer development. (44 refs)

78-6800 Mesotheliomas Induced by Sterigmatocystin in Wistar Rats. (Eng) Terao, K. (Res. Inst. Chemobiodynamics, Chiba Univ., Inohana 1-8-1, Chiba 280, Japan). *Gann* 69(2): 237-247; 1978.

The direct carcinogenic potency of sterigmatocystin (SMC)

to the peritoneum after repeated ip injections was investigated in male Wistar rats. Three groups of rats received ip injections of SMC, O-acetylsterigmatocystin (AcO-SMC), dihydrosterigmatocystin (dihydro-SMC) 1 x/wk for 23 weeks and they were observed for 80 wk. Only SMC produced mesothelioma in 20/40 rats given a total dose of 20-25 mg. No mesotheliomas were found in rats injected with AcO-SMC or dihydro-SMC. Both epithelioid and mesenchymal mesotheliomas were induced by SMC. Hepatocellular carcinomas were found in one rat treated with SMC and five given AcO-SMC. These results suggest that SMC is a potent carcinogen when administered ip. Although both dihydro-SMC and SMC formed fine, needlelike crystals when injected ip, dihydro-SMC did not produce any mesotheliomas. Dihydro-SMC has no double bond in the terminal furan ring; this double bond has been postulated as an important determinant of the acute toxicity and carcinogenicity of aflatoxin B₁ in rats. It is suggested, therefore, that the carcinogenicity of SMC to the peritoneum may be related more closely to the presence of this double bond than to its physical form in the peritoneal cavity. (28 refs)

78-6801 Induction by Degraded Carrageenan of Colorectal Tumors in Rats. (Eng) Wakabayashi, T. (Res. Inst., Nippon Chemiphar Co., Ltd., Misato-shi, Saitama, Japan); Inagaki, T.; Fujimoto, Y.; Fukuda, Y. *Cancer Lett* 4(3): 171-176; 1978.

The carcinogenicity of degraded carrageenan derived from the red seaweed *Eucheuma spinosum* was examined in Sprague-Dawley rats. In the first experiment, rats were divided into four groups of 30 males and 30 females each: Group 1, 2, and 3 received 10%, 5%, and 1% carrageenan in the diet, respectively, for up to 24 mo, and Group 4 served as a control. The rats were sacrificed at various intervals up to 24 mo after the start of the experiment. A total of 59/60 Group 1 and 12/60 Group 2 rats developed colorectal squamous metaplasia; 19/60 and 53/60 rats, respectively, developed colorectal tumors. The tumors were squamous cell carcinomas, adenocarcinomas and adenomas; two Group 1 rats and one Group 2 rat had metastases of squamous cell carcinomas to the retroperitoneal lymph nodes. In a second experiment, 20 animals of each sex were given a 5% aqueous solution of degraded carrageenan in the drinking water for 15 mo. Metaplasia was noted in all 40 rats, and 11 developed tumors. In addition to the tumor types found in the first experiment, one myosarcoma was also observed. In the third experiment, rats were divided into three groups of 15 males and 15 females each. Group 1 was given 5 g/kg and Group 2 1 g/kg of degraded carrageenan by stomach tube for 15 mo. Metaplasia was noted in all Group 1 rats and in 11/30 Group 2 rats. Adenocarcinomas and adenomas were noted in eight Group 1 animals. No colorectal metaplasia or tumors were noted in control rats in all three experiments. These findings indicate that degraded carrageenan is carcinogenic to the colorectal epithelium of the rat. (9 refs)

802 The Use of Short-Term Tests to Measure the Preventive Action of Reducing Agents on Formation and Activation of Carcinogenic Nitroso Compounds. (g) Lo, L. W. (Cancer Res. Centre, Univ. British Columbia, Vancouver V6T 1W5, Canada); Stich, H. F. *Mutat* 57(1): 57-67; 1978.

effect of reducing agents on the nitrosation of methylhydrazine (MG) and on the in vitro activation of dimethylnitrosamine (DMN) was examined in cultured human fibroblasts. The reducing agents were sodium ascorbate, cysteine, glutathione, and propyl gallate. The addition of sodium ascorbate to an NaNO_2 and MG mixture resulted in reduced DNA repair synthesis. The inhibitory action of sodium ascorbate on nitrosation of MG was also observed when the extent of chromosome aberrations was measured and when the colony-forming capacity of human fibroblasts was estimated. A repair synthesis of cultured human fibroblasts incubated with a rat liver microsomal activation system and DMN was greatly reduced in the presence of the reducing agents. The inhibitory effect could have been exerted during activation of DMN, or it could also be due to the trapping of free radicals formed during activation. The results do not distinguish between these two possibilities. Alkaline sucrose gradient analysis showed that sodium ascorbate inhibited the shift to smaller DNA fragments that was observed when cultured cells were exposed to liver microsome-activated DMN. These results indicate that DNA repair synthesis is a suitable short-term test for studying the numerous interactions between several carcinogenic agents and for estimating the capacity of inhibitory agents to affect formation and activation of chemical carcinogens. PHYSICAL CARCINOGENESIS

- 78-6803 **Malignant Melanoma of Skin and Sunspot Activity (Letter to Editor).** (Eng) Wigle, D. T. (Bureau Epidemiology, Lab. Centre Disease Control, Health and Welfare Canada, Ottawa, Canada K1A 0L2). *Lancet* 2(8079): 38; 1978.

Studies in the US and Canada showed that the incidence of malignant melanoma during 1935-75 varied cyclically, with the peaks correlating closely with periods of peak sunspot activity. The increased flux of cosmic rays during peak sunspot activity may destroy stratospheric ozone, so that more UV radiation reaches the earth's surface. (no refs)

- 78-6804 **Re: "Mathematical Models of Age and Ultraviolet Effects on the Incidence of Skin Cancer among Whites in the United States" (2 Letters to Editor).** (Eng) Lee, J. A. (Dept. Epidemiology, Sch. Public Health, Univ. Washington, Seattle, WA, 98195); Fears, T. R.; Scotto, J.; Schneiderman, M. A. *Am J Epidemiol* 107(3): 259-262; 1978.

Discrepancies between the regression coefficients for the incidence of nonmelanoma skin cancer and malignant melanoma with increasing age have implied that both these conditions are related to annual dose rather than cumulative lifetime UV exposure. It is suggested, however, that the similarity of the regression coefficient relating latitude and the coefficient relating age to the incidence of nonmelanoma skin cancer indicates that these tumors are produced by the cumulative effect of UV damage; this cumulative relationship may also hold for melanoma. In a rebuttal, it is held that since a flat age/nonmelanoma incidence is not found, neither melanoma nor nonmelanoma incidences are directly related to total UV exposure. It is suggested that nonmelanoma incidence is related to the cumulative UV dose and that melanoma incidence is related to the annual UV dose. (14 refs)

- 78-6805 **Interaction of Near-Ultraviolet Radiation and Irradiated L-Tryptophan in the Production of Mutations in *Escherichia coli*.** (Eng) Webb, R. B. (Div. Biological and Medical Res., Argonne Natl. Lab., Argonne, IL, 60439); Yoakum, G. H.; Perou, J.; Eisenstark, A. *Mutat Res* 51(3): 427-432; 1978.

The interaction between near-UV radiation and preirradiated tryptophan (TP) in *Escherichia coli* growing in chemostat cultures was studied. Near-UV radiation alone produced T5-resistant mutants in *E. coli* WP2 culture at a rate of 25.3×10^{-8} mutant/cell/day/watt m^{-2} . It produced 59.5×10^{-8} mu-

tant/cell/day/watt m^{-2} in the excision-deficient strain WP2. When TP was present in the culture during near-UV treatment, the rate of mutagenesis was increased two-fold for strain WP2 and seven-fold for strain WP2s. In the absence of near-UV radiation, TP increased the mutation rate by a factor of 1.3 in strain WP2 and by a factor of 1.7 in strain WP2s. The presence of unirradiated TP (5-10 mg/liter) reduced the rate of near-UV mutagenesis. The data suggest that the nonmutagenic repair of lesions produced by the interaction of components of TP and near-UV radiation requires the *uvrA* + endonuclease. (20 refs.)

- 78-6806 **Effects of Dietary Constituents on Ultraviolet Light-mediated Carcinogenesis.** (Eng) Black, J. S. (Photobiology Lab., Veterans Admin. Hosp., Houston, TX, 77030); Chan, J. T.; Brown, G. E. *Cancer Res* 38(13): 1384-1387; 1978.

The effects of dietary supplements of antioxidants and enzyme inducers on UV-mediated carcinogenesis in female hairless mice were investigated. The animals received either a (1) regular, balanced, laboratory meal, (2) regular meal supplemented with 0.05% (wt/wt) phenobarbital, (3) regular meal with disulfiram (2 mg/g meal), (4) regular meal with 0.5% (wt/wt) butylated hydroxytoluene (BHT), or (5) regular meal with 0.1% (wt/wt) reduced glutathione. At the end of 17 wk, the animals in Group 3 were transferred to a regular meal because of wt loss. After 10 days, the mice received UV radiation treatments 5 days/wk through week 17. The initial suberythemal dose was 0.84 joule/cm²/day; it was increased every 2 wk by 0.34 joule/cm² until a daily dose of 2.1 joules/cm² was given. An accumulative dose of 152 joules/cm² was administered. The reduced glutathione diet had no effect on tumor incidence, but the BHT, phenobarbital, and disulfiram diets all significantly suppressed the initiation and development of actinic lesions and tumors. Analysis of the percentage of animals bearing lesions and tumors, percentage of animals bearing tumors, and numbers of tumors/animal indicated that disulfiram provided the greatest protection. Tumor inhibition thus appears to be due to the induction of systemic physiological responses. (39 refs)

- 78-6807 **Inhibition of UV-induced DNA Repair at Different Steps by Quinacrine and Anthralin.** (Eng) Kulkarni, M. S. (Lab. Molecular Biology, Univ. Alabama at Birmingham, AL, 35294); Yelding, K. L. *Biochem Biophys Res Commun* 83(4): 1531-1537; 1978.

The effects of anthralin (AT) and quinacrine (QA) on DNA

er synthesis were evaluated in L1210 cells, a mouse lymphoma line. The cells were labeled with ^3H -thymidine, irradiated with UV light, and incubated for 15 or 45 min with or without QA or AT (both, 50 μM). The appearance and disappearance of single-strand breaks was followed by neutral sedimentation in neutral sucrose gradients. QA reduced the reduction in nucleoid sedimentation rate resulting from UV irradiation. After 15 min of post-UV incubation with QA, these nucleoids still sedimented like those from nonirradiated cells. With 45 min post-UV incubation, however, the sedimentation profile resembled that of irradiated cells. After 15 min of post-UV incubation without QA. These findings suggest that QA inhibits the UV endonuclease step in DNA repair. AT apparently increased the extent of single-strand breaks seen at 15 min post-UV incubation. There was no evidence for repair after 45 min post-UV incubation with AT, as indicated by an increased nucleoid sedimentation rate. However, AT enhanced the initial appearance of nicked DNA, followed by a return to normal, but QA delayed the nicking process. Although both agents inhibit repair synthesis, they produce different biological effects. (25 refs)

6808 Mutagenicity and Carcinogenicity of 8-MOP/UV A in Cell Cultures. (Eng) Burger, P. M. (Inst. Dermatology, Univ. Medical Centre, State Univ. Leiden, Leiden, Netherlands); Simons, J. W. *Bull Cancer (Paris)* 65(3): 281-282; 1978.

ants deficient for the enzyme hypoxanthine-guanine-phosphoribosyltransferase (HGPRT) were selected in V-79 Chinese hamster cells and in human skin fibroblasts (HSF) after application of the photochemotherapeutic (PUVA-therapy) regimen of 8-methoxypsoralen (8-MOP) (10 $\mu\text{g}/\text{ml}$) and UV irradiation (0-600 J/m ^{2}). In the V-79 cells, there was a linear relationship between UV dose and mutation frequency. However, with respect to varying doses of 8-MOP, a constant number of induced mutants (5.5×10^{-8} per μg 8-MOP/ml per J/m ^{2} per unit dose) was detected. HSF also yielded a constant number of induced mutants/unit dose of 8-MOP (3.3×10^{-8} per unit dose for dividing cells and 0.6×10^{-8} /unit dose for nondividing cells). If these results are extrapolated to human skin cells, it is predicted that 7.4×10^{-5} mutants/unit dose for dividing cells and 1.4×10^{-5} mutants/unit dose for nondividing, (or a total of 1.7×10^{-5} mutants induced per unit dose of PUVA therapy) may be expected to arise. A carcinogenic effect (the induction of cell transformation in C3H/3T3 mouse cells) was also observed. (12 refs)

6809 8-Methoxypsoralen as a Frameshift Mutagen in Bacteria and Chinese Hamster Cells in the Skin—Implications for Genetic Risk in Man (Meeting Abstract). (Eng) Bridges, B. A. (MRC Cell Mutation Unit, Univ. Sussex, Falmer, Brighton, England); Mottershead, R. A.; Arlett, C. F. *Mutat Res* 53(2): 156; 1978. (no refs)

78-6810 Characterization of Sister Chromatid Exchange Induction by 8-Methoxypsoralen plus Near UV Light. (Eng) Latt, S. A. (Genetics Div., Childrens Hosp. Medical Center, 300 Longwood Ave., Boston, MA, 02115); Loveday, K. S. *Cytogenet Cell Genet* 21(4): 184-200; 1978.

Factors influencing the induction of sister chromatid exchanges (SCE's) in Chinese hamster ovary (CHO) cells by 8-methoxypsoralen (8-MOP) + near-UV light were investigated. Exposure of CHO monolayers to approx 6×10^{-6} M 8-MOP or UV light (up to 2×10^4 ergs/mm ^{2} , primarily at 365 nanometers) prior to bromodeoxyuridine (BUDR) treatment had little effect on SCE frequency. However, irradiation of cells shortly after 8-MOP addition resulted in a marked increase in SCE's that was dependent on 8-MOP dose and UV dose, but not on the interval between the two. SCE induction by 8-MOP + UV light was compatible with cell survival over multiple cycles. Study of cells that had undergone three cycles of BUDR incorporation indicated that 8-MOP + UV light increased SCE formation during the third cycle. Thus, cells surviving treatment included those damaged and responding with an increase in SCE's. Both the frequency and location of SCE's induced at different times within the DNA synthesis period varied in a manner that indicated that exchange induction was restricted to regions that replicated during or after DNA damage. (56 refs)

78-6811 Inflammatory Reactions Induced by Ultraviolet Irradiation. (Eng) Greaves, M. W. (Inst. Dermatology and St. John's Hosp. Diseases of the Skin, Homerton Grove, London E9 6BX, England); Hensby, C. N.; Black, A. K.; Plummer, N. A.; Finchman, N.; Warin, A. P.; Camp, R. *Bull Cancer (Paris)* 65(3): 299-303; 1978.

Human skin irradiated with different wavelengths of the UV spectrum in the presence and absence of anti-inflammatory drugs was examined pharmacologically. In all experiments, human abdominal skin was irradiated; it was examined visually for erythema, and exudate from irradiated cells was collected at different times after irradiation and analyzed by bioassay using the cascade superfusion technique, by radioimmunoassay, and by gas-liquid chromatography-mass spectrometry. Unirradiated skin from the same subject was used as the control. Blood flow (BF) changes were also measured by photoelectric plethysmography. After irradiation with six times the minimal erythema dose (MED) of UVC [< 290 nanometers (nm) in wavelength], the levels of arachidonic acid (ARA) and prostaglandins (PG)E $_2$ and F $_2$ were all increased (1.5-3.0 times control), reaching a max at 18-24 hr, but returned to control levels by 48 hr, by which time the erythema had also subsided. When the PG inhibitor indomethacin (IM) was administered in divided doses beginning 48 hr before irradiation, the levels of PGE $_2$ and PGF $_2$ were both held to the control level, but ARA levels were enhanced in both irradiated and nonirradiated skin. IM caused a reduction in BF that correlated with a reduction in visual erythema. Irradiation with 3 MED of UVB (290-320 nm) also

produced peaks in levels of ARA, PGE₂, PGF₂ and other ARA metabolites at 24 hr (5 to 20 times control), which returned to control values by 48 hr. Erythema did not decrease at 48 hr, however, and IM treatment produced only a small change in BF in irradiated skin while apparently completely suppressing PG activity. UVA (320-400 nm) treatment of patients after administration of 8-methoxypsoralen produced no changes in PGE₂ or PGF₂ levels in irradiated areas, but ARA levels were again increased at 24 hr. It is suggested that increased levels of PGE₂ protect epidermal cells from mutagenic action of UVB by increasing cellular levels of cyclic AMP and thus reducing the vulnerable pool of actively dividing cells. (16 refs)

78-6812 Detection of DNA Repair in Nuclei Isolated from Human Cultured Cells (Meeting Abstract). (Eng) Robison, S. H. (Dept. Pathology, Thomas Jefferson Univ., Philadelphia, PA); Fansler, B. S. *J Cell Biol* 79(2, part 2): 137a; 1978. (no refs)

78-6813 Quantitative Changes in Respiratory Enzyme Activity in Premalignant Lesions and Experimentally Irradiated Skin. (Eng) Pearse, A. D. (Dept. Medicine, Welsh Natl. Sch. Medicine, Heath Park, Cardiff, Wales); Marks, R. *Bull Cancer (Paris)* 65(3): 351-356; 1978.

The morphological and cell kinetic findings were compared with metabolic changes within the epidermis of patients exposed to solar radiation to investigate the earliest changes in UV-induced neoplasia. Quantitative enzyme histochemical techniques were employed to examine lesional and paralesional skin from four patients with solar keratoses and one with Bowen's disease. Buttock skin was also sampled from these patients to compare the lesional sun-exposed skin with non-sun-exposed skin. Succinic dehydrogenase (SDH) activity was evenly distributed in buttock skin, and there was very little change in total sun-exposed epidermal SDH activity, but it was significantly reduced in the granular cell layer in lesional and paralesional skin of all patients with solar keratoses. Glucose-6-phosphate dehydrogenase (G6PDH) epidermal total activities were increased in both lesional and paralesional skin compared with buttock epidermis in all patients. In all skin samples G6PDH activity was preferentially increased in the granular cell layer. Lactate dehydrogenase (LDH) activity did not show a difference in localization in any tissues studied. When buttock skin of five healthy subjects was irradiated 10x during a 14-day period with 1-2 minimum erythematous doses of 290-400 nanometer, UV irradiation, SDH activity dropped approx 50% in the granular skin layer, but was unchanged in basal layer and total activities. Additionally, G6PDH activity increased significantly in the total epidermis and basal cell layer and somewhat in the granular cell layer after irradiation. It is suggested that these findings may serve as a model for persistent UV light exposure leading to epidermal damage in man. (2 refs)

78-6814 Experimentally Induced Intestinal Metaplasia in Wistar Rats by X-Ray Irradiation. (E) Watanabe, H. (Dept. Cancer Res., Res. Inst. Nuclear Medicine and Biology, Hiroshima Univ., Kasumi 1-2-3, Hiroshima, 734, Japan). *Gastroenterology* 75(5): 796-799; 1978.

The induction of intestinal metaplasia with Paneth cells and intestinal marker enzymes in Wistar rats by local x-irradiation is described. The gastric region of 5-wk-old female Wistar rats was irradiated daily with 500 rads of x-rays up to a total of six times. Goblet cells and marker enzymes of small intestine, such as lactase, trehalase, and maltase, appeared in the pyloric region of the glandular stomach of rats from the first week after final irradiation. Intestinal-type crypts without Paneth cells were observed at 8 wk, sucrose activity at 26 wk, and intestinal metaplasia with Paneth cells at 71 wk. The number of goblet cells, intestinal type crypts and Paneth cells increased with age. Gastric adenocarcinoma did not develop after irradiation. These studies suggest that a small dose of carcinogen might cause only intestinal metaplasia and that increasing the dose level might result in carcinoma associated with metaplasia or, in the case of higher doses, carcinoma alone. 78-6815 Acute Myelomonocytic Leukemia after Irradiation and Chemotherapy for Ewing's Sarcoma. (Eng) Smithson, W. A. (Dept. Pediatrics, Mayo Clinic, Rochester, MN); Burgert, E. O.; Childs, D. S.; Hoagland, H. *Mayo Clin Proc* 53(11): 757-759; 1978.

A 16-yr-old boy was diagnosed with acute myelomonocytic leukemia 16 mo after the start of irradiation and chemotherapy for Ewing's sarcoma of the upper right leg. The primary lesion was treated with a daily midplane dose of 200 rads x-rays for 25 sessions over 29 days (total, 5,000 rads). Beginning at the same time, vincristine (VCR: 2 mg/m², max dose 2.0 mg) and cyclophosphamide (CP: 500 mg/m²) were given weekly for 10 wk, followed by a 4-wk rest period. Then doxorubicin (0.015 mg/kg/day) was given for 5 days, followed by resumption of the weekly VCR and CP therapy for 5 wk. Four cycles of triple-agent chemotherapy were administered. Fourteen months after the initial presentation, a portion of the right lung involved by metastatic disease was resected and the lungs were treated with a total of 1,800 rads of x-rays in 12 fractions over 16 days. Simultaneously, doxorubicin (DR: 30 mg/m²/day) was given for 3 days and repeated once in 3 wk. Two months after the lung resection, the Hb level decreased and undifferentiated blasts appeared in the peripheral blood; the total WBC count was 2,500/mm³ with 1% blasts. DR therapy was continued for 3 mo, at which time the percentage of blasts increased to 38% of a total WBC count of 40,000/mm³. At death, there was no clinical evidence for active Ewing's sarcoma. Although nothing in this case report suggests the need to modify the current approach to Ewing's sarcoma, it does signal the need for surveillance for second neoplasms of all types. (21 refs)

78-6816 **Otolaryngologic Sequelae of Radiation Therapy.** (Eng) Kupperman, G. L. (Univ. Massachusetts, Amherst, MA); Kleiner, H.; Stageman, D. L.; Martinelli, D. *Am J Otolaryngol* 57(11): 510-515; 1978.

The ears, nose, throat, and hearing of 100 persons who had been exposed to head, neck, or chest irradiation at least 10 years previously were examined in an attempt to document the long-term effects of radiation treatment. There was no evidence of clinical carcinoma in the ear, nose, or throat structures of any of the patients. Temporomandibular-joint diseases were found in three patients without the common historical physical findings usually found. One patient had bilateral enlargement of the submaxillary glands and two had unilateral enlargement. Few cases of conductive hearing loss or middle-ear disease were observed. Nine of 27 patients with sensorineural hearing loss gave no history of excessive noise exposure or ototoxic drug therapy. The uncommonly high number of patients with this type of hearing loss indicates there may be some relationship to previous irradiation. (16 refs)

78-6817 **Effect of Some Nonradioactive and Radioactive Chemicals on Spleen Structure.** (Rus) Anomareva, T. V. (Res. Inst. Radiation Hygiene, Leninabad, USSR); Merkushev, G. N. *Arkh Anat Gistol Embriol* (4): 47-52; 1978.

To evaluate the effect of common environmental pollutants on spleen structure, mice and rats received a series of radioactive (^{137}Cs , ^{226}Ra , ^{89}Sr , ^{65}Zn) and nonradioactive [$\text{Pb}(\text{NO}_3)_2$, BeCl_2] nuclides, hexamethylenediamine (HMDA), and chloromethylmercury (CMM) in their drinking water for 1-2 yr. The compounds were given in concentrations (slightly greater than av and max permissible doses). Chronic exposure to ^{226}Ra and ^{225}Ra (total absorbed dose 0.3 and 5.4 rads, respectively), HMDA, and CMM enhanced cell proliferation in the red pulp. Structural rearrangement of the spleen tissue was accompanied by hyperplasia of the lymphoid tissue. Hyperplasia of the hematopoietic stem cells and enhanced plasma cell proliferation were detected after exposure of the rodents to ^{226}Ra , ^{89}Sr , ^{65}Zn , and BeCl_2 . At the end of experiment, the animals had a marked decrease in immune reactivity that coincided with aplasia of the lymphatic component of the spleen. (17 refs)

78-6818 **On the Mechanism of "Dissolution" in Liquids of PuO_2 by Alpha Decay.** (Eng) Fleischer, R. (General Electric Res. and Development Center, Schenectady, NY, 12301); Raabe, O. G. *Health Phys* 35(4):545-548; 1978.

Subparticle formation by alpha decay of plutonium-239 in plutonium oxide particles was studied by the nuclear track technique to locate the sites of deposition of fissionable atoms

or groups of atoms. Fission was induced on a high-purity quartz detector by thermal neutrons, and the individual tracks were revealed by chemical etching. Analysis of the results indicated that in a vacuum, at the most, a single ^{239}Pu atom was ejected with the uranium-235 recoil nucleus. Therefore, direct spraying-out of multiatom fragments does not occur. The most plausible model of the previously observed subparticle formation in water is that a damaged region is produced in the original particle and that the damage is subsequently released by exposure to water. 78-6821 **Estimation of Risk for Lung Cancer Induced by Inhaled Alpha Emitting Radionuclides (Meeting Abstract).** (Eng) Mahaffey, J. A. (Battelle, Pacific Northwest Lab., Richland, WA, 99352); Sanders, C. L. *Pharmacologist* 20(3): 175; 1978. (no refs)

78-6822 **Factors Affecting the Mobility of Plutonium-238 Dioxide in the Rat.** (Eng) Stradling, G. N. (Natl. Radiological Protection Board, Harwell, Didcot, Oxon, England); Ham, G. J.; Smith, H.; Cooper, J.; Breadmore, S. E. *Int J Radiat Biol* 34(1): 37-47; 1978.

A major factor influencing the movement of plutonium-238 from lungs to blood after the administration of oxide suspensions to female inbred rats via intubation was the presence of 0.001- μm -diameter particles. In a polydisperse suspension of particles, this fraction increased with time, probably because of fragmentation of larger particles induced by alpha decay. The rate of this process could account for the greater transportability in vivo of plutonium-238 relative to plutonium-239 when the oxides were inhaled. In blood, 0.001- μm -diameter plutonium-238 oxide particles underwent a rapid reaction to form a low-mol-wt species before plutonium was complexed with transferrin and citrate ions. The filtration of this species through the kidneys may explain the observed enhanced urinary excretion of plutonium relative to administered plutonium citrate. The mechanism of urinary excretion and the relationship between cumulative urinary excretion and body content for plutonium-238 were similar to those

previously observed for plutonium-239, even though different methods of preparation of the oxides were used (calcination of the oxalate, $^{238}\text{PuO}_2$; condensation of the metal vapor, $^{239}\text{PuO}_2$). (25 refs.)

78-6823 Studies on the Uptake of Plutonium from Major Indian Soils and Its Distribution in Plants.

(Eng) Vyas, B. N. (Biology and Agricultural Div., Bhabha Atomic Res. Centre, Trombay, Bombay 400 085, India); Mistry, K. B. *J Environ Qual* 7(4): 533-536; 1978.

Studies of the plant uptake of plutonium from three major Indian soil types showed that the highest amount of Pu was absorbed from acidic laterite soil, followed by alluvial soil and medium-black alkaline soil. Pu concentration ratios in beans and maize ranged from 1.5 to 9.6×10^{-4} for aerial tissues and from 13.9 to 15.3×10^{-4} for roots. In mature bean plants, the Pu distribution showed a marked acropetal gradient. (19 refs)

78-6824 Size Fractionation Methods: Measuring Plutonium in Respirable Dust. (Eng) Hayden,

J. A. (Rockwell International, Rocky Flats Plant, P.O. Box 464, Golden, CO, 80401). *Science* 202(4369): 753-754; 1978.

Four soil fractionation methods were used to separate three size fractions of two soil samples in order to evaluate the inhalation hazard of soil contaminated with plutonium. Increasing amounts of soil mass and Pu activity (0.5%-38% and 7%-84%, respectively) remained in the soil fraction $<10 \mu\text{m}$. The two samples showed similar trends in the changing Pu content of this fraction, the change being highly dependent on the fractionation method used. (5 refs)

78-6825 Influence of Injected Mass of Plutonium on Its Biological Distribution. (Eng) Guilmette, R. A.

(Inhalation Toxicology Res. Inst., P.O. Box 5890, Albuquerque, NM, 87115); Lindenbaum, A.; Friedman, A.; Sullivan, J.; Moretti, E.; Russell, J. J. *Health Phys* 35(4): 529-536; 1978.

The distribution and retention in mouse tissues of an injected mass of plutonium were investigated using four α -emitting Pu isotopes of differing specific activities: ^{236}Pu ($532 \mu\text{Ci}/\mu\text{g}$ Pu), ^{239}Pu ($0.0613 \mu\text{Ci}/\mu\text{g}$), ^{242}Pu ($0.0039 \mu\text{Ci}/\mu\text{g}$), and ^{244}Pu ($1.93 \times 10^{-5} \mu\text{Ci}/\mu\text{g}$). Female B6CF₁/Anl mice 88 days old, were injected iv with $1 \mu\text{Ci}/\text{kg}$ of ^{236}Pu , ^{239}Pu , ^{242}Pu , or $0.3 \mu\text{Ci}/\text{kg}$ of ^{244}Pu . Groups of five animals receiving each isotope were sacrificed 4-96 days after injection, and the following tissues were analyzed radiochemically by α -liquid scintillation counting for Pu content: liver, spleen, kidneys, lungs, lymph nodes, thigh muscle, ovaries, femurs, and tibias (marrow samples from both tibias were analyzed). In all the tissues analyzed, the early distribution and retention of ^{236}Pu ,

which was injected at a mass level (2 nanograms/kg) equivalent to 20% of the max permissible body burden (MPBB) of ^{239}Pu , did not differ from those of ^{239}Pu , even though injected masses differed by $>8,000$. Retention of the isotope of lower specific activity, ^{242}Pu and ^{244}Pu , which were injected at mass equivalents of 28,000 and 99,000 times the MPBB of ^{239}Pu , respectively, was generally three to six times higher than retention of ^{236}Pu and ^{239}Pu in the soft tissues. These results suggest the occurrence of an aggregation of ^{242}Pu and ^{244}Pu in vivo. They also suggest that the use of metabolic data obtained in animal studies with high levels of injected ^{239}Pu allows valid extrapolation downward to at least the level of an MPBB exposure. (13 refs)

78-6826 Radiation Leukemia in C57BL/6 Mice. Correlation of Altered Expression of Terminal

Deoxynucleotidyl Transferase to Induction of Leukemia

(Eng) Pazmino, N. H. (Cancer Biology Program, National Cancer Institute, Frederick Cancer Res. Center, Frederick, MD, 21501); Mullan, R.; Ihle, J. N. *J Exp Med* 148(5): 1338-1350; 1978.

In a study of the effects of irradiation on early thymic differentiation, terminal deoxynucleotidyl transferase (TdT) activity was measured in C57BL/c mice irradiated with total body x-rays 1, 3, or 4 x/wk, beginning at age 1 mo. Early radiation schedule resulted in a 60%-80% loss of thymocytes at 1 wk post-treatment, but the subsequent repopulation of the thymus was dose dependent. Peak TdT I and II activities (expressed as percentage of nonirradiated controls) in thymus and bone marrow decreased dramatically after a single 175-rad irradiation, but they returned to normal values by 4 wk. Recovery of thymus TdT activity after two or three 175-rad doses took longer, and in the bone marrow there was only 50% recovery. Four doses reduced activity to undetectable levels, and no TdT was detected in bone marrow for at least 18 wk. Radiation-induced thymic lymphomas in C57BL/c mice were TdT-positive; high levels of thymus TdT activity were detectable only in overtly leukemic mice, regardless of the time after irradiation. Bone marrow-reconstitution studies immediately after the last radiation abrogated the leukemic effect, and TdT levels were normal 6 wk after reconstitution. Studies of the effects of 4 x 175 rads on mice of various ages showed that susceptibility to leukemia induction and ability to recover normal TdT activity were age-dependent. TdT activity was induced in bone marrow B cells from thymectomized mice given a nonleukemic radiation dose (1×350 rads) but not in B cells from mice given 4 x 175 rads. This indicates that a leukemogenic radiation dose eliminates or alters bone marrow stem cell population inducible for TdT. Since the loss of the TdT stem cell was thymus-independent, the primary effect of irradiation occurs in the bone marrow. (10 refs)

78-6827 Chronic Myelogenous Leukemia Development After Thymic Irradiation. (Eng) Shimaoka,

Medicine B, Roswell Park Memorial Inst., Buffalo, Sokal, J. E. In: *Third International Symposium on the Prevention and Detection of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): (part 1): 1193 pp; 819-830; 1977.

patients with Philadelphia (Ph') chromosome-positive chronic myelogenous leukemia (CML) and a history of thymic irradiation are presented. The first patient underwent thoracic irradiation for breathing difficulties and a widened mediastinum on chest x-ray at 3 mo of age. Three of 100 rads in air were given every other day, for a total of 100 rads. He developed leukemia 18 yr later; chromosome analysis revealed 46XY with a single Ph' chromosome in all metaphases prior to the blastic stage, after which 47XY with two Ph' chromosomes gradually became the sole karyotype. The second patient was given three doses/wk of 132 rads in air to the thorax and an enlarged thymus at the age of 2 mo, for a total dose of 100 rads. Leukemia developed at the age of 22 yr; blast karyotyping revealed a mode of 45 chromosomes (a deletion of one of the Group C chromosomes) and a single Ph' chromosome in all metaphases. It is concluded that both patients had radiation-induced CML. (39 refs)

28 **Behaviour of Murine Lymphosarcoma Cells During Prolonged Cultivation In Vivo.** (Eng) Kovacs, V. (Inst. Biophysics, Czechoslovak Acad. Sci., Brno 12, Czechoslovakia); Drasil, V. *Folia Biol (Praha)* 24(4): 253-263; 1978.

Transplantable lymphosarcoma growing as a free suspension in the peritoneal cavity of isologous hosts was isolated after fractionated irradiation of C57BL mice (4 x 160 R at 2-wk intervals). During a 14-yr cultivation period, the modal number of tumor chromosomes declined from 41-42 to 39, the mean survival time of tumor hosts decreased, and the resistance of the tumor cells increased slightly. Strain specificity remained unchanged. (25 refs)

29 **Estimation of Life Shortening Resulting from Radiogenic Cancer per rem of Absorbed Dose.** Gotchy, R. L. (Radiological Assessment Branch, U.S. Environmental Protection Agency, Washington, DC, 20555). *Health Phys* 35(4): 563-565; 1978.

The amount of life shortening (LS) from the cancer that may be expected from a radiation dose equivalent to 1 rem (roentgen-equivalent-man) was estimated. Equations are given for estimating the LS for a given age cohort. The av LS for each age cohort was estimated by summing all the years of life lost for each age cohort over the entire population. The total LS associated with all cancer types for total body irradiation was derived from the sums of av LS by cancer

type. The total LS per million man-rem is 3,200 yr for the general public. The av loss of life expectancy per individual is 1.2 days/rem. An upper-bound estimate of the av LS of radiation workers per 5-rem dose equivalent was calculated using the 20- to 70-yr population. The av loss of life expectancy for this group for all types of cancer was calculated as 0.63 day/man-rem. It is believed, however, that the actual age distribution of nuclear workers may be skewed toward the younger years. Therefore, the LS of occupationally exposed radiation workers in the nuclear industry is expected to lie between 0.63 and 1.2 days/rem. (4 refs)

78-6830 **Late Effects after Incorporation of the Short-lived α -Emitters ^{224}Ra and ^{227}Th in Mice.** (Eng) Muller, W. A. (Institut für Biologie Gesellschaft für Strahlen- und Umweltforschung mbH, D-8042 Neuherberg, W. Germany); Gossner, W.; Hug, O.; Luz, A. *Health Phys* 35(1): 33-35; 1978.

Dose dependence and temporal distribution of osteosarcomas (OS's) and other malignancies were investigated following single and repeated ip injections of ^{224}Ra of varying activity and single injections of ^{227}Th in NMRI mice. The highest concentration of ^{224}Ra occurred in the long bones, followed by the vertebral column, especially the lumbar spine. After a single injection of ^{224}Ra (1.0-50 $\mu\text{Ci/kg}$, 30-1,500 rads), the OS incidence ranged from 7% to 22% (at 360 rads) in females vs 1.3% in controls. Males had a max incidence of 8.5% at 750 rads (dose range, 5-50 $\mu\text{Ci/kg}$, 150-1,500 rads) vs 0% in controls. A single injection of ^{227}Th in females produced a max incidence of 60% at 1,000 rads. Fractionated application of ^{224}Ra resulted in a higher overall incidence of OS than that from a single injection of the same mean skeletal dose. The highest tumor incidence (> 90%) was observed with the lowest activity per injection, 0.5 $\mu\text{Ci/kg}$ 2 x/wk for 36 wk (total, 1,080 rads). Tumor incidence was also increased when the same mean skeletal dose was distributed over a longer treatment period. When 0.5 $\mu\text{Ci/kg}$ was given 2 x/wk for 36 wk, a 92% OS incidence resulted at 17 mo, but 0.5 $\mu\text{Ci/kg}$ 2 x/wk for 12 wk resulted in only a 46% incidence at 23 mo. OS's occurring with single-dose treatments at the higher doses were located mainly in the head bones; these treatments also increased the incidence of ossified fibromas. Fractionated doses and lower single doses generally produced osteosarcomas in sites other than the head. An earlier occurrence of leukemia was seen in some ^{227}Th -treated groups and in one group given repeated ^{224}Ra injections. (34 refs)

78-6831 **Toxic Autonomous Thyroid Nodule Following Neck Irradiation.** (Eng) Scott, R. S. (Medical Unit, Princess Margaret Hosp., Christchurch, New Zealand); Brownlie, B. E.; Bremner, J. M. *Aust NZ J Med* 8(5): 521-522; 1978.

A 37-yr-old man with history of neck irradiation in childhood

presented with thyrotoxicosis due to an autonomous thyroid nodule. Adjacent to the nodule was a radiation scar from radiotherapy administered 35 yr previously. The long latent period is not unusual, in that thyroid abnormalities have been observed > 30 yr after radiation. Hemithyroidectomy was performed, and histological examination excluded malignant change. (6 refs)

- 78-6832 Radiation Induced Cancer in the Head and Neck Region.** (Eng) Matsumura, Y. (Div. Head and Neck Surgery, Natl. Kyushu Cancer Center, Fukuoka, Japan); Nomura, Y.; Eguchi, S.; Horie, A. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 807-818; 1977.

Twelve patients with radiation-induced cancer, 8 initially treated for benign conditions (Group A) and 4 initially treated for malignant tumors (Group B), were analyzed. The primary tumors in the latter group were reticulum cell sarcoma of the maxilla, squamous cell carcinoma of the larynx (2), and nasopharyngeal carcinoma. At the time of therapy, the average of the Group A patients was 19 yr, that of the Group B patients 44 yr. However, the mean latent interval for Group A was 33 yr, vs only 13 yr for Group B; no cancer developed < 7 yr after the initiation of radiation therapy. Although the radiation dose was not known for some patients, it was estimated that those in Group A received 2,000-5,000 rads, those in Group B 6,000-8,000 rads. Damage to the head and neck skin in Group A patients included fibrosis, stigma, irregular pigmentation, and leukoderma, but Group B patients had only a slight dermatosis. The difference in damage is suggested to be due to the radiation dose, source, and field. Histologically, the radiation-induced cancers were generally anaplastic. They spread diffusely and were of uniform thickness. The radiation-induced cancers are proposed to arise by the two-stage mechanism. The possibility of cancer developing in irradiated patients after a certain latent interval is distinct; these patients should be monitored carefully. (23 refs)

- 78-6833 Contamination of the Home Environment by Patients Treated with Iodine-131: Initial Results.** (Eng) Jacobson, A. P. (Dept. Environmental and Industrial Health, Univ. Michigan Sch. Public Health, Ann Arbor, MI, 48109); Plato, P. A.; Toerock, D. *Am J Public Health* 68(3): 225-230; 1978.

Twin-sodium iodide-radiation detectors were used to analyze iodine-131 transfer from thyroid patients to their families. The study included seven families with 17 persons, 11 of whom were under age 16. Direct radiation exposure of family members due to the proximity of the radioactive patients

ranged from 0.17 to 126 mR/day (natural background radiation is 0.35 mR/day). The range of max activity of iodine-131 in the thyroids was 92-110,000 picocuries, and it resulted in thyroid dose equivalents of 4-1,330 milliroentgen-equivalent-man. Based on recent estimates of thyroid cancer, the latter dose equivalent could double the risk of thyroid malignancy in children over what is expected normally. Such a risk implies the addition of 10 induced cases to the 10 natural occurring cases per million people per year. (20 refs)

- 78-6834 Fate of Inhaled Transuranic Oxides (Meeting Abstract).** (Eng) Adee, R. R. (Battelle, Pacific Northwest Lab., Richland, WA, 99352); Sanders, C. L.; Halsey, J. G. *Pharmacologist* 20(3): 276; 1978. (no refs)

- 78-6835 Development of Osteosarcoma in Rats After Irradiation.** (Eng) Solheim, O. P. (Norsk Hydro Inst. Cancer Res., Oslo, Norway). *Acta Radiol [Theor (Stockh)]* 16(5): 433-446; 1977.

Tissue abnormalities preceding the development of osteogenic sarcoma were determined in inbred male rats exposed to ^{90}Sr (in equilibrium with its daughter isotope ^{90}Y) radiation with activities of 0, 0.05, 0.2, 0.67, or 1.32 $\mu\text{Ci/cm}$. The animals were exposed to the radiation for various times ranging from 4 to 360 days and then sacrificed at times ranging from 4 to 540 days. In the medullary cavity, the main effect of the irradiation was a slow and dose-dependent replacement of the hematopoietic elements by fat. Neither extensive fibrosis nor irregular nontumorous bone was found in the marrow cavity of any animal exposed to continuous irradiation. After termination of irradiation, the hematopoietic tissue was reformed. In the cortical bone, the number of osteocytes decreased at a dose-dependent rate; this decrease continued after the radiation was discontinued. Osteoclasts were found on the periosteal surface of all bones exposed for 14-45 days but they were rarely found on the endosteal surface. The endosteal surfaces were always lined by resting osteoblasts after exposure to at least 0.42 Gray unit/day (all groups above 0.05 $\mu\text{Ci/cm}$). A total of 22 tumors were noted: 4 in the 0.2-, 12 in the 0.67-, and 12 in the 1.32- $\mu\text{Ci/cm}$ groups. Nineteen of these tumors were sarcomas and 10 were osteogenic sarcomas. Malignant proliferation began after approx 180 days of irradiation. Osteogenic sarcomas had their centers at the endosteal surface. The adjacent bone marrow was nearly aplastic, but the endosteum was thickened by fibroblasts and osteoblasts. The number of osteocytes in the adjacent bone was greatly reduced. It is suggested that radiation injury accumulated in osteogenic cells until some mechanism involved in the control of proliferation and differentiation failed. (7 refs)

- 78-6836 Preliminary Studies of the In Vitro Cellular Effects of Asbestos and Fine Glass Dusts.** (Eng) Sincok, A. M. (Dept. Human Genetics and Biometry, Univ.

London, London NW1 2HE, England). In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Ten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4 (Book B), pp. 941-954; 1977.

These hamster cells that had been cloned from a single line cell and checked for a total modal variation of were incubated with various samples of asbestos (0.1 ml) for 48 hr and then subjected to genetic analysis. With of the asbestos samples (S.F.A. chrysotile and U.I.C.C. dolomite), there was a high level of aberration, with > 50% of cells analyzed being karyotypically abnormal. The other asbestos samples also showed significant levels of genetic abnormality. No significant genetic damage was observed in cells treated with coarse fiberglass. A fine glass fiber sample (code 100), which contained fibers within the diameter length ranges of asbestos, also produced a significant level of aberration in treated cells. Both chemical leaching and mechanical milling of asbestos fibers significantly reduced the ability of asbestos to induce in vitro genetic damage. These results indicate the importance of physical morphology in the induction of genetic damage by asbestos. They indicate that this system could be used to grade fine dusts on the basis of induced genetic aberration. (10 refs)

837 Malignant Mesothelioma Arising after Direct Application of Asbestos and Fiber Glass to the Pericardium. (Eng) Churg, A. (Dept. Pathology, Sch. Medicine, Univ. California, San Francisco, CA, 94143); Warnock, J.; Bensch, K. G. *Am Rev Respir Dis* 118(2): 419-424;

A 57-year-old man developed a malignant mesothelioma 15 yr after he had been treated for angina pectoris by dusting of the pericardial cavity with a mixture of fibrous dusts. Electron diffraction and microprobe analysis indicated that approximately 67% of the fibers were tremolite and anthophyllite asbestos and the remainder were fiber glass. This is believed to be the first human malignant mesothelioma associated with direct mesothelial contact with fibrous dusts. (14 refs)

838 Mortality after Long Exposure to Cumingtonite-Grunerite. (Eng) McDonald, J. C. (TUC Health Research Inst. Occupational Health, London Sch. Hygiene

and Tropical Medicine, Keppel St., Gower St., London WC1, England); Gibbs, G. W.; Liddell, F. D.; McDonald, A. D. *Am Rev Respir Dis* 118(2): 271-277; 1978.

The causes of death of 657/660 former cumingtonite-grunerite workers were investigated to determine if exposure to these minerals carried an increased risk of respiratory tract cancer. Excess mortality with a clear dust-exposure relationship was found for pneumoconiosis and respiratory tuberculosis, but there was no convincing evidence of an increase in respiratory cancer. 78-6839 Inhalation Studies with Polyurethane Foam Dust in Relation to Respiratory Tract Carcinogenesis. (Eng) Thyssen, J. (Institut für Toxikologie der BAYER AG, 5600 Wuppertal 1, W. Germany); Kimmerle, G.; Dickhaus, S.; Emminger, E.; Mohr, U. *J Environ Pathol Toxicol* 1(4): 501-508; 1978.

Male and female Sprague-Dawley rats inhaled freshly generated polyurethane foam dusts (8.65 mg/m³ air) for 6 hr/day, 5 days/wk, over a 12-wk period. The exposure had no apparent effect on appearance, behavior, body wt, or life-span, and there were no indications of a carcinogenic effect of the dusts on the respiratory tract. (11 refs)

VIRAL CARCINOGENESIS

- 78-6840 Cell-free Translation of Avian Sarcoma Virus RNA: Suppression of the *gag* Termination Codon Does Not Augment Synthesis of the Joint *gag/pol* Product.** (Eng) Weiss, S. R. (Dept. Microbiology, Univ. California, San Francisco, CA, 94143); Hackett, P. B.; Oppermann, H.; Ullrich, A.; Levintow, L.; Bishop, J. M. *Cell* 15(2): 607-614; 1978.

The effect of yeast suppressor transfer RNA's (tRNA's) on the cell-free translation of two viral gene products (Pr76*gag* and P180*gag/pol*) from the 38S messenger RNA (mRNA) of avian sarcoma virus (ASV) was studied. Although the synthesis of P180*gag/pol* was not enhanced by the suppressor tRNA's, and the use of amber suppressor tRNA reduced the synthesis of Pr76*gag* and resulted in the synthesis of a new 80,000-dalton polypeptide (P80) that contained the antigenic determinants of *gag*. Studies using chemical inhibitors of the initiation of translation demonstrated that P80 was generated by the addition of amino acids to the carboxy terminus of Pr76. The data indicate that the ASV *gag* gene is terminated by an amber codon, UAG, and that suppression of this termination signal does not lead to uninterrupted translation from *pol*. A second termination signal about 120 nucleotides from the UAG termination appears to define the length of P80. Thus, at least two suppression events would be necessary to synthesize P180. This argues against the hypothesis that suppression of nonsense codon(s) at the end of the *gag* gene is responsible for the synthesis of P180 in the ASV-infected cell. (28 refs)

- 78-6841 Characterization of Transformation-Sensitive Membrane-Proteins in Chick Embryo Fibroblasts Transformed with Avian Sarcoma Virus.** (Eng) Isaka, T. (Dept. Viral Oncology, Cancer Inst., Kami-Ikebukuro, Toshima-ku, Tokyo 170, Japan); Ikawa, Y.; Yoshida, M. *Virology* 90(2): 330-343; 1978.

A membrane polypeptide of 90,000 daltons (P90) found in increased amounts of chick embryo fibroblasts transformed by avian sarcoma virus was characterized, and its accumulation in transformed cells was studied. Compared with normal cells, there was a marked increase in the amount of P90, some increase in P79, and a decrease in P200 in transformed cells. Autoradiography showed that P90 had exactly the same isoelectric point as a polypeptide of 91,000 daltons (P91). Comparison of the peptide maps of P90 and P91 showed that the two polypeptides had very similar primary structures. P91 was shown not to be a glycoprotein, and it appeared to be the glycosylated form of P90. However, there was no conversion of P91 to P90 by deglycosylation. It is concluded that P91 is formed by glycosylation of the growing polypeptide

P90 on polysomes, that P90 is formed in the absence of glycosylation, and that the completed polypeptides are not interconvertible. (26 refs)

- 78-6842 A Simple Method for Rapid Purification of Avian Sarcoma Virus Supercoiled DNA by Selective Precipitation of Infected Cell Chromatin.** (Eng) Goto, R. V. (Dept Microbiology, Coll. Physicians and Surgeons, Columbia Univ., New York, NY, 10032). *Anal Biochem* 90(1): 256-261; 1978.

A simple and effective method of partially purifying avian sarcoma virus (ASV) supercoiled (form I) DNA from infected quail tumor cells (QT6) consists of lysing infected nuclei in water and precipitating the resulting chromatin with sodium chloride. This method offers some advantages over the Hirt procedure in that low-mol-wt viral DNA can be extracted rapidly and only 1%-2% cellular DNA is found in the viral fraction, even when the total number of cells to be processed is as high as 3.4×10^9 . The total amount of ASV-specific DNA recovered was 70%-100% of that recovered by the Hirt method. Similar results were obtained with simian virus 40 (SV40)-infected cells were processed by two methods, with the chromatin method extracting about 85% of the SV40 DNA extracted by the Hirt procedure. The efficiency of the two methods was compared by monitoring the recovery of ASV DNA after final purification. Approximately 3×10^9 QT6 cells were labeled with ^3H -thymidine immediately after ASV infection. The nuclei were prepared and divided into two parts, and each half was subjected to one of the purification procedures. Complete purification of ASV form I DNA, as monitored by alkali sucrose gradient analysis, required only two steps by the chromatin method, whereas at least three or four steps, including two CsCl-propidium iodide equilibrium gradient centrifugation steps were required to eliminate contaminating cellular DNA in the Hirt supernatant. Because of the extremely low levels of host cell DNA in the postchromatin fraction, the method is particularly suitable for purifying low-mol-wt viral DNA's, such as Rous tumor virus and SV40 DNA's. - 78-6843 *env* Gene of Chicken RNA Tumor Viruses: Content of Conservation in Cellular and Viral Genomes.** (Eng) Fujita, D. J. (Cancer Res. Lab., Univ. Western Ontario, London, N6A 5B7 Ontario, Canada); Tavaré, Varmus, H. E.; Bishop, J. M. *J Virol* 27(3): 465-474; 1978.

Molecular hybridization studies with DNA complementary to *env* gene sequences of chicken leukosis-sarcoma v

s (cDNA) were performed with a variety of avian s to examine the natural distribution and possible ori- of viral *env* genes. The results indicate that nucleotide nces closely related to cDNA are present in chicken but not in other avian DNA's tested or in calf thymus salmon sperm DNA's. These results are in marked con- to experience with the transforming gene (*src*) of avian ma viruses, for which homologs have been demonstrat- the DNA's of all avian species tested and also in the 's of other vertebrates. The *env* gene sequences were to be present in the DNAs of both chick helper fac- sitive and chick helper factor-negative (chf-) chicken at a level of one copy per haploid genome. The presence v gene sequences in chf- DNA suggests that the chf- type does not result from a major deletion of *env* gene nces, and it is consistent with the existence of mech- is for the regulation of *env* gene expression. Thermal uration studies were used to further examine the ology between the *env* genes of representatives of viral roups A to E. The results indicate that the hybrids ed between cDNA and RNA's of subgroup A to E es are closely matched. This suggests that a substantial on of the *env* genes of viruses of subgroups A to E con- of shared, closely related sequences and that these genes bly have a common evolutionary origin. (36 refs.)

844 Isolation and Characterization of the Envelope Glycoprotein of an Avian Osteopetrosis Virus: t of Host Cell on Antigenic Reactivity. (Eng) Van El- L. J. (Rockefeller Univ., 1230 York Ave., New York, 10021); Smith, R. E. *Virology* 90(1): 80-89; 1978.

physical and antigenic properties of the surface glyco- in (gp85) of avian myeloblastosis-associated virus [V-2(O)] were compared with those of avian myeloblasto- rus (AMV) gp85. Sodium dodecyl sulfate-polyacryla- gel electrophoresis and guanidine hydrochloride col- chromatography indicated that the gp85's of the two es were qualitatively similar, but that MAV-2(O) con- d approx 3.46 times more gp85 than AMV. When the of MAV-2(O) grown in chick embryo fibroblasts (CEF) examined by competition radioimmunoassay (RIA) us- rabbit anti-AMV gp85 serum, it exhibited 100- to -fold less reactivity than the AMV glycoprotein. In con- MAV-2(O) isolated directly from the serum of osteope- chickens competed efficiently. If MAV-2(O)-infected n of osteopetrotic chickens was replicated in CEF for 1 t subsequently lost its ability to compete in RIA with V. AMV itself did not compete effectively when grown EF, but it did so when grown in myeloblasts. MAV-2(O) ed from serum or CEF competed equally in RIA's using erum against B77 virus gp85, and glycoproteins from -grown MAV-2(O) and serum AMV showed equal ivity to the B77 antiserum. These results suggest MAV-2(O) and AMV gp85 show similar host- ndent glycosylation patterns in vivo and different erns when the viruses are grown in cultured CEF. (refs)

78-6845 Fractionation of Proteins from Rous Sarcoma Virus and Avian Myeloblastosis Virus by Isoelectric Focusing. (Eng) Mach, O. (Inst Molecular Genetics, Czechoslovak Acad of Sciences, Prague 6, Czechoslovakia); Sovova, V.; Cerna, H. *Folia Biol (Praha)* 24(4): 233-241; 1978.

The technique of isoelectric focusing in pH gradients was used to isolate proteins from Rous sarcoma virus and avian myeloblastosis virus. The purified major group-specific (gs) protein p27 (pI = 9.1) and gp86 (pI = 5.3) were obtained after disruption of virus with 1% nonionogenic detergent in the presence of 6M urea. Proteins p10, p15, and p19 were present in the same pH range (pI = 6.8). A strongly basic, immunologically active protein, presumably p12, was found in the alkaline region at pH 10.8. These proteins fully retained their immunological activity. On the other hand, in the acidic region between pH 4 and 5, strong precipitates were regularly found. These precipitates were complexes that were formed by interaction of the acid components of ampholines with the viral proteins during isoelectric focusing. Almost all viral proteins were present, differing only in quantity. The complexes were stable in 1% nonionogenic detergent with 6M urea. They were dissociated with 1% sodium dodecyl sulfate and 5M urea, and they had no immunological activity. The methods of virus disruption and the possibility of formation of the ampholine-viral protein complexes are discussed. (23 refs)

78-6846 Assay for Early Cytoplasmic Effects of the *src* Gene Product of Rous Sarcoma Virus. (Eng) McClain, D. A. (Rockefeller Univ., New York, NY, 10021); Maness, P. F.; Edelman, G. M. *Proc Natl Acad Sci USA* 75(6): 2750-2754; 1978.

The *src* gene product of Rous sarcoma virus (RSV) was as- sayed by microinjection of cytoplasmic extracts of chick em- bryo fibroblasts transformed by the Prague strain of RSV (subgroup A) into normal mouse 3T3 fibroblasts and then examining the actin-containing structures in these cells by immunofluorescence microscopy. Microinjection of these cytoplasmic extracts, but not extracts of normal cells, caused a dissolution of the 3T3 cell microfilament bundles that was max within 30 min. The activity could still be measured after a tenfold dilution of the cytoplasmic extracts (14 mg/ml original protein concentration). The activity was trypsin-sen- sitive and it was destroyed by boiling, but it was not RNase-sensitive. Protein synthesis was not required for the dissolution. Microinjected cytoplasts prepared from normal 3T3 cells also dissolved the microfilament bundles, indicating that the cell nucleus was not required for expression of activi- ty. Extracts made from fibroblasts transformed by RSV hav- ing a temperature-sensitive mutation in the *src* gene were also temperature-sensitive in this assay. Thus, the activity of extracts from cells infected with *src* mutant virus, but not from cells infected with wild- type virus, was destroyed either by in vitro incubation of the extract at the nonpermissive temperature before

injection or by incubation of recipient cells at the nonpermissive temperature after injection. It is concluded that the microinjection assay can detect a cytoplasmic activity coded for by the *src* gene RSV and that an early direct or indirect target of the *src* gene product is the cytoskeleton and cell motility system. This result is discussed in relation to the hypothesis that submembranous arrays of microfilaments, microtubules, and their associated proteins interact with cell-surface receptors to form a surface-modulating assembly that functions as a key regulator of cell growth. (13 refs)

- 78-6847 Linkage of the Endogenous Avian Leukosis Virus Genome of Virus-producing Chicken Cells to Inhibitory Cellular DNA Sequences.** (Eng) Cooper, G. M. (Sidney Farber Cancer Inst., Dept. Pathology, Harvard Medical Sch., Boston, MA, 02115); Silverman, L. *Cell* 15(2): 573-577; 1978.

To account for the inefficient transcription and lack of infectivity of endogenous Rous-associated virus-O (RAV-O) DNA of uninfected virus-producing (V+) cells, it was proposed that the endogenous RAV-O genome was linked to a cis-acting control element of cellular DNA that inhibited its transcription. The prediction of this model that shearing the DNA of uninfected V+ cells might convert the endogenous RAV-O genome to an infectious form by separating it from the control element was tested. The DNA of uninfected V+ chicken cells was infectious at a low level. In addition, the infectivity of RAV-O DNA of uninfected V+ cells was increased approx sixfold by shearing the DNA to the approx size of the viral genome. In contrast, shearing the DNA of RAV-O-infected cells reduced its infectivity 5- to 20-fold. Thus, the infectivity of endogenous RAV-O DNA relative to the infectivity of DNA of RAV-O infected cells was increased approx 60-fold by shearing. These results suggest that the endogenous RAV-O genome of V+ chicken cells is linked to cellular DNA sequences that inhibit its infectivity in transfection assays, as predicted by the cis-acting control element model. Alternative interpretations, however, such as the possibility that shearing leads indirectly to internal rearrangements in the viral genome, cannot be excluded. Since the infectivity of sheared DNA of uninfected cells was approx 0.3% of the infectivity of sheared DNA of RAV-O-infected cells, the size of the control element was roughly estimated at 0.1%-1% in the size of the RAV-O genome, or 10-100 nucleotide base pairs. These findings suggest that the endogenous viral genome of uninfected V+ chicken cells is linked to specific inhibitory cellular DNA sequences, and they provide further evidence consistent with the model of endogenous viral gene regulation. (17 refs)

- 78-6848 Evidence That the Transforming Gene of Avian Sarcoma Virus Encodes a Protein Kinase Associated with a Phosphoprotein.** (Eng) Levinson, A. D. (Dept. Microbiology, Univ. California, San Francisco, CA,

94143); Oppermann, H.; Levintow, L.; Varmus, H. E.; Bishop, J. M. *Cell* 15(2): 561-572; 1978.

Immunoprecipitation with rabbit tumor antisera to avian sarcoma virus (ASV) was used to isolate a phosphorylated protein of mol wt 60,000 daltons (pp60). This protein appeared to be encoded by the *src* gene responsible for the induction and maintenance of neoplastic transformation. Phosphorylation of pp60 could be accomplished in vitro with extracts of ASV-infected cells. With a temperature-sensitive conditionally lethal mutation in *src*, phosphorylation of the pp60 protein was temperature-sensitive. Since the mutant *src* was not expressed at the restrictive temperature, phosphorylation of pp60 must be required for its function as the putative effector of *src*. Immunoprecipitates prepared with extracts of ASV-infected cells and the rabbit tumor antisera contained a protein kinase activity that catalyzed phosphorylation of the heavy chain of immunoglobulin molecules, using either ATP or guanosine triphosphate as phosphate donor. It appears that the protein kinase may also be encoded in *src* and that the enzymatic activity may be an intrinsic property of pp60. Phosphorylation of pp60 in cellular extracts was inhibited by calcium ionophores, whereas the immunoprecipitable kinase activity was not, suggesting that the kinase responsible for pp60 phosphorylation may be distinct from that encoded in *src*. The data suggest that phosphorylation of specific cellular targets may account for transformation of the host cell by *src*. (36 refs)

- 78-6849 Ascorbic Acid Retards RNA-Tumor Virus Infection of Avian Cells in Culture (Meeting Abstract).** (Eng) Bissell, M. J. (Lab. Chemical Biodynamics, LBL, Univ. California, Berkeley, CA, 94720); Hatie, C.; Farnsworth, D.; Schwarz, R.; Soo, W. J. *J Cell Biol* 79(2, part 1): 401a; 1978. (no refs)

- 78-6850 Limited Host Range of Avian Tumor Viruses in Pigeon Cells.** (Eng) Meyers, P. (Dept. Microbiology, Mayo Clinic and Mayo Medical Sch., Rochester, MN 55901); Ritts, G. D.; Heise, J. M.; Qualtiere, L. F. *Virology* 90(1): 162-165; 1978.

Show Racer (SHR) and White Corneau (WC) pigeon embryo fibroblasts (PEF) were found to be virtually resistant to infection with Rous sarcoma virus (RSV) of subgroups A, B, C, D, and E. Focus assays were performed on five SHR PEF and six WC PEF cultures, using nine RSV strains, representing all five subgroups. PEF were absolutely resistant to subgroups A and E and 2/3 subgroup B viruses. Schmidt-Rupprecht (SR)-RSV, subgroup B, plated to some degree on many PEF, but its max plating efficiency (EOP) was 0.0002 relative to standard chicken embryo fibroblasts (CEF). Subgroup C viruses plated poorly, but SR-RSV, subgroup D, plated relatively high titers in several PEF, the max EOP being 0.001 relative to CEF. Although SHR is an outbred and WC is an inbred strain, there was little difference in PEF resistance to RSV. (16 refs)

1 Binding of Tryptophanyl-tRNA to the Reverse Transcriptase of Replication-defective Avian Viruses. (Eng) Panet, A. (Dept. Virology, Hebrew Hadassah Medical Sch., Jerusalem, Israel); Weil, G.; R. *J Virol* 28(2): 434-443; 1978.

NA polymerase activity and the binding to tryptophan transfer RNA of the reverse transcriptase (TR) from five avian sarcoma virus mutants, two (LA 335 and LA 336) carrying an early replication lesion and three (LA 343, and LA 672) defective in a late replication lesion, were examined. Compared with the activities of the wild-type parents, both RT activities were found to be reduced in LA 335 and LA 336. When the other mutant viruses were grown at the permissive temperature, the RT activities were nearly as heat-stable as those of the wild-type parents. At the nonpermissive temperature, however, both RT activities were reduced in LA 338, LA 343, and LA 672. The relative amounts of RT antigen in these virions was determined by a competition immunoassay, it was found that the mutants contained reduced amounts of RT protein per total protein when harvested at the nonpermissive temperature. Even the infectious virus mutants produced at the permissive temperature always contained less enzyme protein than the wild-type parents. (27 refs)

52 Characterization of Rous Sarcoma Virus *src* Gene Products Synthesized In Vitro. (Eng) Beecher, K. (Tumor Virology Lab., Salk Inst., San Diego, CA, CA); Hunter, T. *J Virol* 28(2): 551-566; 1978.

Cell-free translation products of Rous sarcoma virus (RSV) virion RNA were further characterized by parallel denaturation of the heat-denatured virion RNA's of Prague group B (PR-B), Schmidt-Ruppin subgroup D (SR-D), transformation-defective (td) SR-D RSV in the messenger RNA-dependent reticulocyte lysate system. Two-dimensional analysis of the tryptic peptides of the 17,000 (17K), 25K, and 60K proteins synthesized by PR-B and SR-D RSV, but not td SR-D RNA, revealed that they have overlapping amino acid sequences. However, these products showed strain-specific differences, manifested by their electrophoretic mobility in acrylamide gels and by their tryptic peptides. Virion RNA's coding for the 17K, 25K, and 60K proteins were polyadenylated and they sedimented with maximum S values at about 23S, 19S-20S, and 18S, respectively. Transformation-specific proteins with mol wts of 39K and 33K were also synthesized. These proteins were related to the three proteins, and were synthesized from polyadenylated RSV RNA of approx 21S-22S. RNase T₁-resistant oligonucleotides were analyzed in parallel, and the *src*-specific oligonucleotides were found to be first present in equimolar amounts in gradient fractions sedimenting at 21S-22S. The results suggest that synthesis of the 60K protein is initiated near the 3' end of the *src* gene and that the 39K, 33K, and 17K proteins are initiated internally in the

src gene. All these proteins appear to be initiated independently, but they may have a common termination site. (30 refs)

78-6853 Study of Group-specific Proteins in Mammalian Cells Transformed by Rous Sarcoma Virus.

(Eng) Sovova, V. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Praha 6, Czechoslovakia); Bosch, V.; Cerna, H. *Folia Biol (Praha)* 24(3): 199-205; 1978.

Lysates of rat, mouse, and hamster cells transformed by Rous sarcoma virus (RSV) and labeled with ³⁵S-methionine were examined for the presence of group-specific (gs) proteins by means of antisera, and the size of these molecules was determined by gel electrophoresis. Gs proteins were not detected in any of the immunoprecipitates analyzed. Only in RSH-mix cells (Syrian hamster embryo fibroblasts transformed in vitro by the Schmidt-Ruppin strain of RSV) was there a quantitative difference in the amount of a 70,000-dalton protein. Autoradiograms of simultaneously tested immunoprecipitates of lysates of RSV-transformed chicken cells clearly showed the presence of p27 and, after a short-term labeling period, the gs precursor molecule pr76. In previous experiments using complement fixation, gs proteins were detected in two of the RSV-transformed mammalian cell lines. The most probable explanation for this discrepancy is that the precursor molecule is attached to subcellular structures in mammalian tumor cells. (21 refs.)

78-6854 Analysis of Rous Sarcoma Virus (RSV) RNA Structure by Means of Specific Nucleases.

(Eng) Darlix, J. L. (Departement de Biologie Molculaire, Universite de Geneve, CH-1211-Geneve 4, Switzerland); Spahr, P. F.; Bromley, P. A. *Virology* 90(2): 317-329; 1978.

The effects of *Escherichia coli* RNases III and IV and *Aspergillus oryzae* T₁ ribonuclease and S1 nuclease on Rous sarcoma virus (RSV) 70S and 35S RNA were analyzed by the fingerprinting technique. The viral RNA was very susceptible to both RNases III and IV, with five regions being highly susceptible. Of these five regions, two, represented by T₁ oligonucleotides 13 and 2, are directly related to the initiation sites for reverse transcriptase. A large number of RSV RNA regions excluded from Sephadex G-75 were resistant to degradation by T₁ RNase, with 35S RNA being much less resistant than 70S RNA. Regions of 70S RNA with oligonucleotides 8, 15, and 9 were very resistant to S₁ nuclease; similar results were found with 35S RNA. Large T₁ oligonucleotides were not very susceptible to RNases III and IV, with the exception of oligonucleotides 2 and 18. The results indicate that RSV RNA is a highly structured molecule in which the two 35S subunits are intimately associated via a large number of specific interactions to form the 70S complex. (37 refs)

- 78-6855 Fluorescent Probe Studies of Normal, Persistently Infected, Rous Sarcoma Virus-transformed, and Trypsinized Rat Cells.** (Eng) Burleson, G. R. (Lobound Lab., Dept. Microbiology, Univ. Notre Dame, Notre Dame, IN, 76556); Kulpa, C. F.; Edwards, H. E.; Thomas, J. K. *Exp Cell Res* 116(2): 291-300; 1978.

The fluorescent probes pyrene, pyrene butyric acid, and N-phenyl-1-naphthylamine were used to study membranes of normal rat cells, Rous sarcoma virus (RSV)-transformed cells, cells treated with a proteolytic enzyme, and cells persistently infected with lymphocytic choriomeningitis virus. The lifetimes of excited pyrene and pyrene butyric acid showed only minor changes among normal, transformed, trypsinized or persistently infected cells. However, pyrene, but not pyrene butyric acid, lifetimes were shorter in cell membranes than in homogeneous solvents. The quenching of excited pyrene in cells by quencher molecules was slower than corresponding reactions in homogeneous solutions, indicating that the probe was screened from the quencher by the membrane. Quenching reactions with the pyrene butyric acid probe were similar in cells and homogeneous solvents, which indicated that pyrene and pyrene butyric acid reside in different lipid regions of the membrane. Transformed and trypsinized cells showed increased membrane fluidity, compared with normal and persistently infected cells. Membrane fluidity was determined from the excimer/monomer fluorescence ratios of pyrene and by the polarization of N-phenyl-1-naphthylamine fluorescence. Several techniques distinguished between normal and transformed or trypsinized cells; however, the only parameter unique to RSV transformation was a blue shift of the fluorescence maxima of N-phenyl-1-naphthylamine. This shift, which reflected a less polar environment of N-phenyl-1-naphthylamine in virus-transformed cells, was reversed by trypsinization. Therefore, the shift was apparently due to the presence of a trypsin-sensitive protein unique to the transformed cells. (31 refs)

- 78-6856 Characterization of the Avian Sarcoma Virus Protein p60src.** (Eng) Brugge, J. S. (Dept. Pathology, Univ. Colorado Medical Center, Denver, CO, 80262); Steinbaugh, P. J.; Erikson, R. L. *Virology* 91(1): 130-140; 1978.

The intracellular distribution of the avian sarcoma virus (ASV) protein p60src was investigated in transformed chicken and hamster cells by radioimmunoprecipitation of fractionated cells and by immunofluorescent staining of fixed cells with monospecific antiserum to p60src. The src protein was found exclusively in the cytoplasmic fraction in both a soluble and an insoluble form. Furthermore, the antigenicity of p60src was extremely heat-labile in vitro relative to Pr76, the precursor to the internal structural proteins of ASV. Antibody against p60src in serum from rabbits bearing tumors induced by the Schmidt-Ruppin (subgroup D) strain of ASV did not recognize p60src from cells transformed by other ASV strains, including Prague C, B77, and Bryan (RAV-50).

Reevaluation of the precipitation of p60src from NY68-transformed cells led to the conclusion that there is no reduction in the synthesis or antigenicity of p60src when cells are cultured under conditions nonpermissive for transformation by the mutant virus. (15 refs)

- 78-6857 Large-Scale Production, Concentration and Purification of Rous Sarcoma Virus in Tissue Culture.** (Eng) Dostalova, V. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Prague 6, Czechoslovakia); Hložek, I.; Mach, O.; Lacinova, J. *Folia Biol (Praha)* 24(4): 225-232; 1978.

A method is described for the production of large amounts of purified virus from tissue cultures of chicken cells transformed by the Prague strain of Rous sarcoma virus, subgroup C. The method is based on the use of roller culture bottle precipitation with polyethylene glycol 6000, and purification by zonal centrifugation. Mean yields in cells cultured for 2 wk were 4.9 mg virus/liter of culture medium. (21 refs)

- 78-6858 Long-term Karyological Study of RVP, Tumour Cells Grown In Vitro.** (Eng) Sainarova, I. (Inst. Molecular Genetics, Czechoslovak Acad. Sciences, Prague 6, Czechoslovakia); Svoboda, J. *Folia Biol (Praha)* 24(4): 242-252; 1978.

The RVP₃ cell line established from an in vivo passaged RVP tumor, which originated in a C57BL/6 mouse infected with the Prague strain of Rous sarcoma virus (RSV), was analyzed at different passage levels and characterized virologically and cytogenetically. The RVP₃ cell line has 2-5 medium-sized large metacentric chromosomes; the majority of the mitoses contain about 1 subtelocentric chromosome; and in addition every mitosis contains chromosomal structures corresponding to the group (termed m-ms) that comprises both minute chromatin bodies and microchromosomes. In three RVP₃ monocellular clones with a similar karyotype, the number of m-ms increased proportionally to the total number of chromosomes in individual metaphases. It was established that the RVP₃ cell population does not contain any transmissible agent producing chromosomal changes in mouse cells and that RVP₃ cells are highly malignant. No RSV could be rescued from the clone tested. The possibility that m-ms's are generated by chromosome excision followed by replication and reintegration is discussed. The accompanying recombination events could lead to deletion or loss of proviral sequences adjacent to the region of the chromosome breaks. (11 refs)

- 78-6859 Differentiated Expression of Virus Genome in Mammalian Cells Transformed by Rous Sarcoma Virus.** (Rus) Tatosyan, A. G. (Lab. Leukemia Virology

Res. Center, Moscow, USSR); Kiselev, F. L. *Vopr* 24(10): 9-13; 1978.

ly was designed to attempt to verify the hypothesis that specific RNA in rat XC and TWERC cells murine cells, and hamster XPO cells transformed by Rous virus (RSV), undergoes transcription from different parts of integrated viral genome. Incubation of the RNA product of RSV with RNA isolated from transfected cells revealed a high level of molecular hybridization (80%) with RNA from cells producing gS-antigenic XC cells and helper-dependent TWERC cells) hybridized with a low level of hybridization (10%-13%) with RSV-3 cells. 60 **Demonstration of Marek's Disease Tumor-associated Surface Antigen in Chickens Infected with Noncancerous Marek's Disease Virus and Herpesvirus** (Eng) Schat, K. A. (Dept. Avian and Aquatic Medicine, New York State Coll. Veterinary Medicine, Ithaca, NY, 14853); Calnek, B. W. *J Natl Cancer Inst* 55:855-857; 1978.

presence of Marek's disease tumor-associated surface antigen (MATSA) was demonstrated on spleen cells from P-line chickens inoculated 5-6 days earlier with herpesvirus of turkeys (HVT) and SB-1 (a noncancerous Marek's disease virus). Fluorescence, which was restricted to the cell membrane, was more intense on cells from SB-1-infected chickens than those from HVT-infected chickens. Antisera against MATSA expressed on five Marek's disease lymphoblastoid cell lines were able to recognize the MATSA present on infected spleen cells. No viral membrane antigens and a low incidence of viral internal antigens could be demonstrated. (16 refs.)

61 **The Herpesvirus of Marek's Disease and Human Cancer.** (Eng) Makari, J. G. (Makari Res. Center, Englewood, NJ, 07631). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer in New York, NY: Vol. 1(part 1): 1193 pp.; 263-278; 1977.

Previously found common antigenicity between glycoprotein (gp) antigens from human cancers and those from spleen cells of chickens with Marek's disease was explored further by a highly sensitive, modified Schutz-Dale technique. A search was made for serum antibodies (ab) to Marek's disease herpesvirus (MDHV) in 141 subjects with and without cancer and for MDHV antigens in the deoxyribose-purified (DPF) of normal and cancerous tissues. Serum antibodies prepared from MDHV were found in 63% of

65 subjects with nonmalignant diseases, 74% of 69 subjects with carcinoma (ca), and 4/7 subjects with melanoma and sarcoma. Serum antibodies to gp antigens prepared from herpes simplex virus types 1 and 2 and Epstein-Barr virus were found in only 4% of 52 subjects with nonmalignant diseases, 9% of 54 subjects with ca, and none of the 5 subjects with melanoma and sarcoma. All 8 subjects with early colon and breast cancer had serum antibodies against MDHV, vs 56% of 18 subjects with late disease. MDHV antigens were found in the DPF of all nine cancer types tested, but not in normal lung DPF or in DPF from fibroid uterus. These antigens were not detected with comparable gp antigens extracted from mouse hepatitis virus and influenza virus or with six control tissue antigens prepared from human and chicken tissues. Certain types of cancer were associated with antigens prepared from various strains of MDHV: ie, colon cancer was associated with the GA strain, breast, ovary, and lung cancer were associated with the CR-64 strain, and liver cancer and lymphoma were associated with the GA-2 strain. The associations were found in both the serum antibody and DPF studies. This was not the case with the gp antigens from the other herpesviruses investigated. (27 refs)

78-6862 **Murine Mammary Tumor Virus Expression During Mammary Tumorigenesis in BALB/c Mice (Meeting Abstract).** (Eng) Pauley, R. J. (Dept. Cell Biology, Baylor Coll. Medicine, Houston, TX, 77030); Socher, S. H. *J Cell Biol* 79(2, part 2): 358a; 1978. (no refs)

78-6863 **Murine Mammary Tumor Virus (MuMTV) Infection of an Epithelial Cell Line Established from C57BL/6 Mouse Mammary Glands.** (Eng) Vaidya, A. B. (Dept. Microbiology and Immunology, Hahnemann Medical Coll., Philadelphia, PA, 19102); Lasfargues, E. Y.; Sheffield, J. B.; Coutinho, W. G. *Virology* 90(1): 12-22; 1978.

An epithelioid cell line (C57MG) derived from the mammary glands of a 23-wk-old C57BL/6 breeder mouse was found to be susceptible to infection by murine mammary tumor virus (MuMTV). After infection of 10^6 C57MG cells/ml with approximately 10^{11} virus particles/ml, there were no changes in all morphological or growth characteristics, but annealing experiments with cellular DNA and complementary MuMTV DNA indicated that the infected C57MG cells had acquired three times as many MuMTV-related DNA sequences as uninfected cells. When high molecular weight cellular DNA was separated from unintegrated relatively low-molecular weight DNA and then hybridized again with complementary MuMTV DNA, the threefold increase was again demonstrated in the high-molecular weight fraction of infected cells vs the noninfected cells. This indicated a high level of MuMTV DNA integration in infected C57MG cells. Infected cells synthesized approximately 150 copies of MuMTV RNA per cell, and the concentration was enhanced by the addition of dexamethasone to the culture medium. Uninfected cells had no observable MuMTV RNA

under any conditions. Infected cells released 80 MuMTV virions/cell/24 hr before dexamethasone stimulation and 240 virions/cell/24 hr after stimulation. Electron microscopy indicated that the virions were indistinguishable from standard MuMTV. Thermal denaturation profiles were inadequate in determining whether the MuMTV produced by infected C57MG cells was of infecting virus or endogenous C57 virus origin. This in vitro infection of in vivo target cells for MuMTV provides an additional useful research tool. (27 refs)

78-6864 The Use of Molecular Hybridization to Track the Mode of Transmission and Distribution of Murine Mammary Tumor Viruses. A Model for Etiologic Studies of Human Breast Cancer. (Eng) Schlom, J. (NCI, NIH, Bethesda, MD, 20014); Colcher, D.; Drohan, W.; Kettmann, R. *Prog Exp Tumor Res* 21: 140-158; 1978.

Molecular hybridization techniques were used to determine whether mouse mammary tumor virus (MMTV) can be introduced into a given mouse via the germ cell line or via a non-germ line mechanism. Labeled 60S-70S RNA from a C3H mouse mammary tumor virus [MMTV(C3H)] was hybridized to an excess of DNA from livers of normal C3H mice, and the unhybridized RNA fraction was isolated. This recycled RNA hybridized to the DNA of C3H mammary tumors, but not to the DNA of C3H livers. Thus, it represents the portion of the MMTV(C3H) genome that is transmitted via a non-germ line mechanism. These sequences were present as provirus in the DNA's of mammary tumors of C3H, RIII, and GR mice, but they were not detected in the DNA's of mammary tumors of C3HfC57BL or BALB/c mice or in the DNA's of normal livers of several mouse strains. Thermal analysis of hybrids also demonstrated qualitative differences in MMTV proviral sequences in different mouse strains. The use of ³H-MMTV complementary DNA indicated quantitative differences in MMTV proviral sequences in different mouse strains and between normal and neoplastic tissues of a given mouse. The complexities of the murine model must therefore be considered in studies dealing with a viral involvement in human breast cancer. (23 refs)

78-6865 Translation of Mouse Mammary Tumor Virus RNA: Precursor Polypeptides are Phosphorylated during Processing. (Eng) Nüsse, R. (Dept. Virology, Antoni van Leeuwenhoekhuis, Plesmanlaan 122, Amsterdam, Netherlands); Asselbergs, F. A.; Salden, M. H.; Michalides, R. J.; Bloemendal, H. *Virology* 91(1): 106-115; 1978.

The synthesis of viral polypeptides of murine mammary tumor virus (MMTV) was studied by pulse-labeling of MMTV-producing cells and by translating MMTV virion RNA in vitro, in *Xenopus laevis* oocytes. Virus-related polypeptides were detected by immunoprecipitation with monospecific antisera against the major viral proteins gp49 and p24 and analysis of the immunoprecipitates

on polyacrylamide gels. In pulse-labeled MMTV-producing cells (Mm5mt/cl), a precursor 73,000-dalton polypeptide was immunoprecipitated by anti-p2 serum (Pr73gag). Pr73gag comigrated with the 73,000 dalton glycosylated precursor for the envelope proteins (Pr73gag) immunoprecipitated by anti-gp4 serum. Pr73gag was, during chase, converted into 76,000-dalton polypeptide that also reacted with the anti-p2 serum (Pr76gag). After prolonged incubation, the mature internal protein p24 was synthesized. Pulse-labeling with ³²P and subsequent chasing revealed that phosphate was incorporated into Pr76gag but not into Pr73gag. Isolated virion 70S RNA of MMTV, microinjected into *Xenopus* oocytes, gave rise to the synthesis of Pr73gag, Pr76gag, and p24, all immunoprecipitated by anti-p24 serum, and the viral core proteins p14 and p10, precipitated by polyvalent anti-MMTV serum. 70S RNA did not instruct synthesis of the viral envelope glycoproteins. (27 refs)

78-6866 Genetic Control of Endogenous Murine Mammary Tumour Viruses Reinvestigated. (Eng) Bentvelzen, P. (Radiobiological Inst. TNO, 151 Lange Kleiweg, Rijswijk, Netherlands); Brinkhof, J.; Haaijman, J. J. *Br J Cancer* 14(10): 1137-1147; 1978.

Milk samples of progeny mice from crosses between mouse strains that differ in the degree of release of endogenous murine mammary tumor virus (MuMTV) were tested for the presence of MuMTV antigens by the Sepharose bead immunofluorescence assay. The results indicated that, compared with nonexpressor BALB/c mouse, a single dominant gene controls the release of MuMTV in C3Hf mouse. However, the low-cancer strain C57BL carries a dominant, epistatic gene that can inhibit virus release in hybrids with C3Hf to a large extent. The high-cancer strain GRS harbors a dominant gene that, in F1 hybrids of all strains tested, causes the release of large quantities of a virus (MuMTV-P) that induces tumors at an early age. Other genetic factors control the release of a lesser oncogenic virus in the GRS strain. The animals tested for MuMTV antigens were subsequently force-bred for mammary carcinoma production. Although there was a good correlation between virus release at a young age and tumor development at a late age, a substantial number of virus-negative mice developed mammary tumors. (3 refs)

78-6867 Expression of Mammary Tumor Virus Antigens in the Male Secondary Genital Organs of the GRS/A Mouse Strain. (Eng) Imai, S. (2nd Dept. Pathology, Nara Medical Univ., Nara, Japan); Imai, N.; Morimoto, J.; Tsubura, Y. *J Nara Med Assoc* 29(3): 503-508; 1978.

Four immunological methods (immunodiffusion, microimmunodiffusion, immunofluorescence absorption, and radioimmunoassay) were compared for their ability to detect mammary tumor virus (MTV) antigen, and a pilot study was

out to correlate the expression of MTV antigen in genital organs to the Mtv-2 gene in GRS/A strain mice. Immunassay was the most sensitive method for detecting MTV antigen. Studies of tissue extracts of the epididymis and the coagulating gland suggested that MTV antigen expression in these organs might be under the control of the 2 gene locus. (20 refs)

868 Involvement of Mouse Mammary Tumor Virus in Spontaneous and Hormone-induced Mammary Tumors in Low-Mammary-Tumor Mouse Strains.

Michalides, R. (Div. Virology, Antoni van Leeuwenhoek Institute, Netherlands Cancer Inst., Amsterdam, Netherlands); Deemter, L.; Nusse, R.; Ropcke, G.; Boot, L. *J Virol* 55:551-559; 1978.

The possible involvement of mouse mammary tumor virus (MTV) in spontaneous and hormone-induced mammary tumors in low-mammary-tumor mouse strains was studied by comparing the amounts of MTV DNA and MTV RNA in mammary tumors, mammary glands, and other organs of mice with and without hormonal treatments. Hormone treatment was performed as follows: four hypophyseal isografts were implanted, two into each kidney, of C3Hf females at the age of 6-8 wk; one hypophysis was implanted into the left side of castrated O20 males at the age of 6-8 wk. Estrone (1 mg/liter) was added to the drinking water throughout the whole life-span of the mouse, and 3 mg of progesterone was given sc. The virus-induced mammary tumors contained 10³ MTV DNA copies in their cellular genome than the amount present in the genome of cells of noninfected tissues. The former also contained larger amounts of MTV RNA than those found in the lactating mammary glands of these animals. Hormone-induced mammary tumors contained the same number of MTV DNA copies in their cellular genome as the other tissues of the animals. Hormone treatment resulted in an increased expression of MTV RNA in the lactating mammary glands, but this enhanced level of MTV expression was not maintained in the hormone-induced mammary tumors. Spontaneous mammary tumors of BALB/c mice did not contain enhanced amounts of MTV DNA or MTV RNA. (27 refs.)

869 An Inquiry into the Involvement of Nonhuman Primate Breast Cancer Viruses in the Human Disease: Experiments in Malignant Breast Ductal Stem Cells.

McGrath, C. M. (Dept. Biology, Michigan Cancer Foundation, Detroit, MI, 48201); Soule, H. D. In: *Mechanisms of Carcinogenesis. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, W. W.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory); Origins of Human Cancer. Vol. 4 (Book 99 pp.; 1287-1303; 1977.

An attempt was made to determine if mouse mammary tu-

mor virus (MMTV)- or Mason-Pfizer monkey virus (MPMV)-related information is expressed in malignant breast ductal cells (MCF-7) and is present as a provirus in malignant cell DNA. Line MCF-7 was derived from cells cloned from pleural effusions of a scirrhous carcinoma, which contained cells with prominent histologic and hormonal markers. MMTV-related RNA was detected upon hybridization (hyb) with MMTV complementary DNA (cDNA) in 0.5 M Na⁺ and under stringent conditions of hyb (hydrolysis with a single-strand-specific nuclease), suggesting extensive sequence homology between MMTV-related RNA in MCF-7 cells and murine breast virus genomic RNA. MMTV-related RNA was not detected in two nonbreast malignant cell lines under identical hyb conditions; ie, MMTV cDNA does not complex nonspecifically with any human cell RNA at the RNA concentrations used. In addition, antigens cross-reactive with MMTV virion antigens were detected in the MCF-7 cells, suggesting that MMTV-related RNA is informational in the malignant breast stem cell. However, MMTV-related DNA sequences were not detected in MCF-7 DNA under hyb conditions capable of detecting one av copy per cell. MPMV-related RNA was not detected in MCF-7 cells using MPMV cDNA representing a minimum of 60% of MPMV RNA, and the major internal protein of MPMV (p27) was not detected by immunofluorescence assay or radioimmunoassay. MPMV sequences were not found in MCF-7 DNA at a significantly higher frequency than that found in normal human cells, which suggests that the normal breast precursor of MCF-7 was not infected by MPMV, at least not in the same manner as that in other human cells. Although the data do not rule out the possibility of information related to MMTV or MPMV in DNA of the human breast carcinoma cells, the inability to detect a major portion of the genome related to either virus in DNA of MCF-7 cells provides a rationale for isolating viruses directly from breast carcinoma cells for use as probes in etiologic studies of breast cancer. 78-6870 The Relative Hydrophobicity of Oncornaviral Structural Proteins. (Eng) Marcus, S. L.

(Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Smith, S. W.; Racevskis, J.; Sarkar, N. H. *Virology* 86(2): 398-412; 1978.

The interaction of the major structural polypeptides of murine mammary tumor virus (MuMTV) and Rauscher murine leukemia virus (R-MuLV) with alkyl-agarose derivatives containing hydrocarbon arms of various lengths was examined. Both R-MuLV and MuMTV polypeptides were selectively adsorbed to octylimino (C₈)-agarose and decylimino (C₁₀)-agarose columns. The proteins were eluted with buffers containing 8.5 M ethylene glycol. In certain cases, the polypeptides could be removed from the columns only by the addition of detergent to the ethylene glyco-containing buffers. By examining the chromatographic behavior of the polypeptides, and the conditions required for their elution, it was possible to determine the relative potential for the hydro-

phobic interaction (degree of hydrophobicity) of each viral protein. The most hydrophobic MuMTV polypeptide was the glycoprotein gp34, p15(E) and the gag precursor prp67 appeared to be the most hydrophobic R-MuLV proteins. The least hydrophobic MuMTV polypeptides were p23 and p16, and those of R-MuLV proteins were the two major internal proteins, p10 and p12. Four degrees of apparent hydrophobicity, from least hydrophobic to strongly hydrophobic, could be discerned by this procedure. The major core proteins (MuMTV p23, R-MuLV p30) of both viruses were slightly hydrophobic, but their major glycoproteins were moderately hydrophobic. The degree of hydrophobicity of oncornaviral polypeptides, as determined by hydrophobic chromatography, to the different subviral components with which the proteins were associated. Hydrophobic chromatography may provide a new parameter for the characterization of oncornaviral polypeptides. (52 refs)

- 78-6871 Source and Hormone-Dependence of GIX-gp70 in Mouse Serum.** (Eng) Obata, Y. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Stockert, E.; Yamaguchi, M.; Boyse, E. A. *J Exp Med* 148(3): 793-798; 1978.

Strain 129 mice (not overt producers of virus) were examined to determine the tissue origin and hormone dependence of serum GIX-gp70 (a 70,000 dalton polypeptide distinguished by the type-specific antigen GIX). The source of GIX-gp70 could not be traced to any organ or tissue that is known to be GIX-positive by serological tests. Hematopoietic tissues were excluded as the source of serum GIX-gp70 by tests with reciprocal radiation chimeras made from 129 and 129-GIX-donors and recipients. Thymus and spleen were excluded because excision of these organs did not affect levels of GIX-gp70 in the serum. The serum of young adult 129 males contained approx four times as much GIX-gp70 as adult 129 females and the levels rose with increasing age in both sexes. Castration of 129 males reduced the level of serum GIX-gp70 to that of females, and the level was fully restored by testosterone. Thus, the epididymis and seminal fluid, although rich in GIX-gp70, do not contribute significant amounts of GIX-gp70 to the serum. The level of GIX-gp70 in the serum of testosterone-treated females, although more than double that of untreated females, did not reach the level of normal males, under the conditions tested. This may signify that GIX-gp70 production in males is subject to imprinting by testosterone in early life. Evidently, the main source of GIX-gp70 is a tissue or organ that is common to males and females, is directly or indirectly responsive to testosterone, and has not so far been identified serologically as GIX-positive. (16 refs.)

- 78-6872 Xenotropic MuLV are Subject to Restriction by the Fv-1 Locus of the Mouse (Meeting Abstract).** (Eng) Gautsch, J. W. (Dept. Cellular and Develop-

mental Immunology, Res. Inst. Scripps Clinic, La Jolla, CA)
Jensen, F. C.; Elder, J. H.; Lerner, R. A. *J Cell Biol* 79(part 2): 406a; 1978. (no refs)

- 78-6873 Wild Rat Type C Virus: Isolation and Characterization.** (Eng) Rasheed, S. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA 90033); Charman, H. P.; Gardner, M. B. *Virology* 89(2): 605-609; 1978.

C-type virus was isolated from a wild male rat (*Rattus rattus*) and compared with the C-type viruses from two strains of laboratory rat. The wild rat was injected sc with 200 mg of 3-methylcholanthrene, and the resulting fibrosarcoma, which developed at the inoculation site within 13 mo, was directly cultured. The wild-rat tumor cells were tested for virus production at various passages by the supernatant RNA-dependent DNA polymerase activity assay. The results of virus purification, neutralization, and interference studies showed that the isolated virus exhibits the general properties of rat leukemia virus (RLV) including the RLV-specific p30 antigen. It showed low infectivity for rat cells and no other species. It was antigenically similar to other RLV strains of laboratory rat origin. It is concluded that a C-type virus genome is potentially activable in fetal rats never subjected to laboratory inbreeding. (12 refs)

- 78-6874 Physicochemical, Biological and Serological Properties of a Leukemogenic Virus Isolated from Cultured RadLV-induced Lymphomas of C57BL/Ka Mice.** (Eng) Declève, A. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Sch. Medicine, Stanford, CA 94305); Lieberman, M.; Ihle, J. N.; Rosenthal, P. N.; Lunn, M. L.; Kaplan, H. S. *Virology* 90(1): 23-35; 1978.

A radiation leukemia virus (RadLV/VL₁) produced by C57BL/Ka cells, which were derived from a RadLV-induced C57BL/Ka mouse thymic lymphoma, was characterized by physicochemical studies with ³H-uridine-, ³H-thymidine- and ³H-leucine-labeled RadLV/VL₁, as well as inhibition of the viral reverse transcriptase (RT) by antiserum against Moloney murine leukemia virus RT, indicated that the isolate was a C-type RNA virus. The virus was not neutralized by antibodies prepared against other ecotropic or xenotropic murine C-type viruses, used singly or in combination, but was neutralized by rabbit and mouse anti-RadLV serum. The inability of RadLV and RadLV/VL₁ to induce cytopathic changes or transformed cell foci in mink lung cell culture even after addition of xenotropic BL/Ka(X) virus, indicated that the in vitro and in vivo host-age patterns of these viruses could not be attributed to the presence of competent or defective mink cell focus-forming virus. In co-infection experiments using live or UV-inactivated viruses, none of the viruses tested was able to interfere with RadLV and RadLV/VL₁. However, purified RadLV/VL₁ protein gp70

ificantly interfered with the infectivity of RadLV and VL/VL₃, indicating that the major envelope glycoprotein of C57BL/Ka thymotropic and leukemogenic viruses is distinct from other tested viruses. This was supported by the fact that in competitive radioimmunoassay for RadLV/VL₃, that used an anti-RadLV/VL₃ antiserum, none of the viruses competed equivalently to RadLV/VL₃ gp71. Other results for the p12 and p30 component of RadLV/VL₃ did not show this specificity. (20 refs)

78-6875 The Pattern of Involvement of Murine Lymphoid Tissues by Primary Lymphomas of Different Cell Lineage. (Eng) Baird, S. (Veterans Admin. Hosp., La Jolla Village Drive, La Jolla, CA, 92161); Raschke, J. *J. Natl. Cancer Inst. Pathol* 9(1): 47-50; 1978.

The metastatic patterns of several different lymphomas were compared with the recirculation pattern of normal T lymphocytes. T and non-T lymphomas were induced in newborn B/c mice by injections of Abelson leukemia virus preparations. Many primary T-cell lymphomas migrated in the lymphoid system in areas occupied by normal recirculating lymphocytes (eg, the periarteriolar white sheath of the spleen and thymus). Other lymphomas lacking T-cell markers did not show this pattern of migration. This lends support to the use of classifying human lymphoid neoplasms as either T- or B-derived on the basis of their surface antigen markers and morphology in lymph nodes. The data indicate that murine lymphomas are good models for studying the metastatic pattern of some human lymphomas under prospective controlled conditions. (3 refs)

78-6876 Genetic and Immunological Controls of Murine Leukemia Viruses in AKR Mice. (Eng) Nowinski, R. C. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104); Baron, J. M. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1977*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1978; 198; 1977.

Low-leukemic AKR mice, low-leukemic C57L mice, and their hybrids were examined for the production of murine leukemia virus (MuLV) p30 antigen, the production of infectious non-oncogenic MuLV (ieMuLV), and the development of immunity against various proteins of the endogenous virion. C57L mice did not produce ieMuLV, and p30 expression in their spleens was low. In contrast, AKR mice produced high titers of ieMuLV, and p30 expression in the spleens was high. F₁ hybrids produced high titers of ieMuLV and expressed high p30 levels in their spleens. Backcross C57L x AKR x C57L F₁ mice genetically segregated for the expression of infectious MuLV and p30: 68% produced ieMuLV, and did not contain detectable virus. This ratio was statisti-

cally compatible with a two-gene model for the control of MuLV. Virus-producing backcross mice expressed high levels of p30; most of the nonproducers expressed low p30 levels, but a minor population expressed high p30 levels. The latter represent a phenotype distinct from that of the AKR and C57L parents. AKR and C57L strains produced low titers of natural antibody (ab) against eMuLV; their F₁ hybrids produced anti-MuLV ab in a higher titer than either of the parents. Progeny of the backcross mice that contained ieMuLV produced anti-MuLV ab's. Thus, the persistent production of ab against high-titered MuLV in these mice did not result in immunological tolerance toward viral antigens. Mice that did not contain ieMuLV could be separated into ab-producing and ab-nonproducing classes. The absence of a detectable ab to MuLV in a mouse was invariably associated with a virus-free phenotype. Overt production of endogenous eMuLV probably served as a major immunogenic stimulus for the production of anti-MuLV ab in these mice. (73 refs)

78-6877 Acquisition of Oncogenicity by Endogenous Mouse Type C Viruses: Effects of Variations in *env* and *gag* Genes. (Eng) Devare, S. G. (Lab. Cellular and Molecular Biology, NCI, Bethesda, MD, 20014); Rapp, U. R.; Todaro, G. J.; Stephenson, J. R. *J. Virol* 28(2): 457-465; 1978.

Competition immunoassays were used to compare the structural proteins of different groups of highly leukemogenic viruses: dual-tropic isolates derived from the thymuses of preleukemic or leukemic AKR mice and strains generated by in vitro or in vivo passage of a weakly infectious endogenous virus of C3H mouse cells. The results show that three AKR-derived isolates and two C3H passage-derived isolates possess *gag* gene-coded proteins immunologically indistinguishable from those of AKR murine leukemia virus. This observation confirms the results of a previous study in which the major structural proteins of several AKR-derived mink cell focus-inducing isolates were found to be similar to those of AKR-MuLV. In contrast, *gag* gene-coded proteins of two other leukemogenic isolates of C3H origin, including one ecotropic and one dual-tropic virus, were indistinguishable from those of Moloney MuLV. All of the highly leukemogenic viruses, including those of AKR and C3H origin, as well as C3H-derived virus, FC clone 3, possessed common envelope glycoprotein antigenic determinants of a class not exhibited by the nononcogenic ecotropic viruses from which they were derived. The results suggest that oncogenic variants of endogenous ecotropic mouse C-type viruses are derived by genetic recombination. This recombinational event appears to involve the acquisition, by different ecotropic viruses, of a common class of endogenous virus-coded envelope glycoprotein determinants that may be required, but not necessarily sufficient, for leukemogenicity. (19 refs)

78-6878 A Target Cell Assay for Friend Virus. (Eng) Steinheider, G. (Albert Einstein Coll. Medicine,

1300 Morris Park Ave., Bronx, NY, 10461); Steeves, R. *Leuk Res* 2(3): 197-200; 1978.

An assay was developed for the in vitro infection and subsequent quantification of the hemopoietic target cells from spleen and bone marrow of DBA/2 mice that can replicate Friend virus (FV). The presence of macroscopic spleen colonies in recipient CDF₁ mice was used to quantify the number of infected FV-releasing cells. DBA/2 mice were bled on two consecutive days and sacrificed. Bone marrow and spleen cells were isolated and cultured with 5×10^4 spleen focus-forming units/ml of FV at 37 C for 1 hr and then injected into CDF₁ mice. After 8 days, the CDF₁ spleens were removed and spleen colonies counted. Inoculation with different dilutions of infected DBA/2 cells revealed a linear relationship between the quantity of infected cells transferred and the number of resulting spleen colonies. Lethal irradiation (5,000 R) of 50% of the infected DBA/2 donor cells before injection yielded 73.8 ± 2.1 colonies from the intact cells but none from the irradiated cells, showing that the production of virus and the generation of spleen colonies requires a living cell and ruling against the passive transfer of cell-adherent virus only. When the numbers of infected spleen and bone marrow cells from bled and unbled DBA/2 donor mice that resulted in spleen colonies in recipient mice were compared, it was concluded that bone marrow had more target cells than spleen and that the hemopoietic stimulus of bleeding was greater in the spleen than in the bone marrow. This assay may prove useful in finding and improving the conditions for true oncogenic transformation by FV in vitro, which was not observed in this experiment. (18 refs)

78-6879 Antibody-induced Loss of Friend Virus Leukemia Cell Surface Antigens Occurs During Progression of Erythroleukemia In F₁ Mice. (Eng) Doig, D. (Hamilton, MT, 59840); Chesebro, B. *J Exp Med* 148(5): 1109-1121; 1978.

The ability of anti-Friend leukemia virus (FLV) serum + rabbit complement (C') to lyse leukemic spleen cells from (B10A x A/WynSn)F₁ and (B10.A x A.BY)F₁ mice was studied. Leukemic cells from 27/28 mice showed high specific lysis (20%-45%) when tested 8-9 days after inoculation of the mice with B-tropic FLV (1,500 focus-forming units iv), but cells of only 5/31 mice had > 20% lysis 30-90 days post-inoculation. Quantitation of FV-induced cell surface antigens (CSA) by absorption of cytotoxic antibodies demonstrated that the antigen levels were 4.5-fold higher in early (8-9 days) leukemic cells than in later cells. No difference in absorption of antibody to H-2d histocompatibility antigens was noted when (C57BL/10 x BALB.B)F₁ anti-(B10.D2 x BALB/c)F₁ (anti-H-2d) serum was absorbed with (B10.A x A/WynSn)F₁ early or late or leukemic spleen cells or with normal cells. There were also no changes in H-2K or H-2D antigens. Membrane immunofluorescence studies confirmed the loss of FV-induced CSA in the later stages of leukemia. Acetone-fixed cells

showed no difference between early or late F₁ leukemic spleen cells when tested for the presence of cytoplasmic antigen with conjugated goat anti-Moloney LV. The decrease in FV-induced CSA could be reversed after adoptive transfer of leukemic cells to lethally irradiated (900 rads) unimmunized congenic hybrid mice, but not after transfer to immunized recipients. When late F₁ leukemic spleen cells were cultured in vitro in the absence of anti-FV antibody, no increase in FV-induced CSA was noted. Conversely, no decrease in FV-induced CSA occurred in early leukemic spleen cells cultured with high concentrations of cytotoxic anti-F serum. The observed decreased antigen expression may represent a tumor cell adaptation to host immune pressures generated during the course of FV leukemia. (19 refs)

78-6880 Biosynthesis and Metabolism of Viral Proteins Expressed on the Surface of Murine Leukemia Virus-infected Cells. (Eng) Ledbetter, J. A. (Fred Hutchinson Cancer Res. Ctr., 1124 Columbia St., Seattle, WA, 98104); Nowinski, R. C.; Eisenman, R. N. *Virology* 91(1): 116-129; 1978.

Viral proteins expressed on the surface of the Friend virus-induced leukemia E(female)G2 were detected by immune precipitation assays from detergent lysates of cells that were labeled by the ¹²⁵I-lactoperoxidase method. These proteins included gp70 and two glycosylated polyproteins that contained antigens coded by the *gag* gene. The 95,000-dalton polyprotein (gpP95*gag*) reacted with antisera against p30, p12, and p10; the 85,000-dalton polyprotein (gpP85*gag*) reacted with antisera against p30 and p12, but not against p10. Neither polyprotein reacted with reverse transcriptase antiserum. GpP95*gag* and gpP85*gag* contained glucosamine only, but gp70 contained both glucosamine and fucose. Tryptic peptide maps of the iodinated polyproteins indicated that gpP95*gag* and gpP85*gag* were highly related. Viral polyproteins with the same electrophoretic mobilities as the cell surface gpP95*gag* and gpP85*gag* were also detected by immune precipitation of lysates from cells that were metabolically labeled with radioactive methionine or arginine. In kinetic studies, gpP95*gag* was labeled rapidly following a 10-min pulse, in contrast, gpP85*gag* was not detected until late in the chase period, suggesting that this glycosylated polyprotein was a processed product of gpP95*gag*. Mapping of arginine-labeled tryptic peptides of different *gag* polyproteins supported this assumption. In fact, peptide mapping with isolated viral proteins demonstrated that gpP95*gag* and gpP85*gag* contained peptides of p30, p15/p12, and p10. The presence of p10 peptides in both polyproteins was unanticipated, since the gpP85*gag* did not react in immune precipitation assays with anti-p10 serum. By peptide mapping, both of the glycosylated polyproteins also appeared highly related to Pr75*gag*, the intracellular precursor to virion *gag* proteins. The data suggest that gpP85*gag* is a glycosylated cell surface form of the primary *gag* precursor Pr75*gag*, and that processing of gpP95*gag* results in the production of gpP85*gag*. (35 refs)

881 **The Integrated Genome of Murine Leukemia Virus.** (Eng) Steffen, D. (Dept. Biology, Center Res., Massachusetts Inst. Technology, Cambridge, 02139); Weinberg, R. A. *Cell* 15(3): 1003-1010; 1978.

Southern gel filter transfer technique was used to characterize the integrated genome of Moloney murine leukemia virus (M-MuLV) and the genomes of the endogenous mouse viruses. A study of 10 clones of rat NRK cells independently infected by M-MuLV indicated a minimum of 15 integration sites into which the M-MuLV provirus could be inserted. No common integration site was observed among these clones. Cells productively infected by M-MuLV acquired multiple proviruses, but infected cells unable to produce virus contained only one M-MuLV provirus. Once established, the integrated genomes were stable for at least two years after reinfection. A spectrum of *Eco*RI-cleaved mouse DNA fragments containing endogenous MuLV genomes was determined through the use of M-MuLV probes. DNA's of different inbred laboratory mouse strains yielded similar provirus patterns, with each strain showing minor characteristic differences. In some instances, mouse cells infected by M-MuLV yielded additional proviruses beyond those seen in uninfected cells. DNA's from three different M-MuLV-induced lymphomas indicated, as in rat cells, multiple possible integration sites. (20 refs)

882 **T1 Oligonucleotide Maps of Moloney and HIX Murine Leukemia Viruses.** (Eng) Faller, D. V. (Dept. and Center for Cancer Res., Massachusetts Inst. Technology, Cambridge, MA, 02139); Hopkins, N. *Virology* 90(2): 265-273; 1978.

Genomes of a HIX virus, its putative ecotropic parent (Moloney IC), and another clonal isolate of Moloney virus (Moloney clone-1) were studied by RNase T1 oligonucleotide analysis. HIX and Moloney IC shared 42 out of 51-53 of their cleavable T1 oligonucleotides, and the two clonal isolates of Moloney virus shared 46 T1 oligonucleotides. Each virus possessed some oligonucleotides not found in the others. Based on oligonucleotide mapping, it was concluded that: oligonucleotides shared by HIX and Moloney viruses probably lie in the same relative positions on their genomes; the oligonucleotides found in Moloney IC but not HIX, and vice versa, are clustered in corresponding regions in the 3' halves of the Moloney IC and HIX maps; and the oligonucleotides that differ between the two clonal isolates of Moloney virus are scattered along the 5' half of the Moloney IC oligonucleotide map. (26 refs)

883 **Host Response Against Oncorna Virus Induced Lymphomas in Mice.** (Eng) Becker, S. (Dept. of Cancer Biology, Karolinska Inst., S-104 01 Stockholm 60, Sweden); Klein, E. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Sym-*

posium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 61-68; 1978.

The host response against oncornavirus-induced lymphomas in mice was first demonstrated by transplantation immunity and then by the presence of antibodies reacting with the cell surface. With the development of in vitro methods and the discovery of various lymphocyte subpopulations, attention was focused on cell-mediated killing effects. Three cell types with killing potential can be distinguished: lymphocytes mediating antibody-dependent killing, sensitized T cells, and natural killer (NK) cells. The reactivity to cell-mediated cytotoxicity in vitro do not, however, correlate. Two serologically cross-reacting lymphoma culture lines (YAC-1 and RBL-5) differ in their sensitivity to cell-mediated cytotoxicity by both NK and sensitized T cells. A cell line selected from YAC for low amounts of Moloney cell-surface antigen recognized by mouse antibodies (YAC-IR) does not show decreased sensitivity to the killing effect of either NK or sensitized T cells. Histocompatibility restriction prevails in short-term cytotoxic tests with sensitized effectors. In cold target inhibition tests with A x C57BL F₁ (H-2a, H-2b); but not C57BL (H-2b), effectors, anti-RBL-5 (H-2b) cytotoxicity was inhibited by YAC-1 (H-2a), indicating the recognition of both H-2a and H-2b target cells. When F₁ effector spleen cells were cultured in vitro in the presence of RBL-5 cells, effector cells against RBL-5 were selected with regard to histocompatibility restriction, as indicated by the fact that YAC-1 cells were not inhibitory. (27 refs)

78-6884 **Biological, Immunological, and Biochemical Evidence that HIX Virus is a Recombinant Between Moloney Leukemia Virus and a Murine Xenotropic C Type Virus.** (Eng) Fischinger, P. J. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Frankel, A. E.; Elder, J. H.; Lerner, R. A.; Ihle, J. N.; Bolognesi, D. P. *Virology* 90(2): 241-254; 1978.

Various characteristics of HIX virus were studied to determine its origin and relationship to other murine C-type oncornaviruses. Cloned amphotropic HIX virus adapted to grow in human RD cells (HIX-RD) could enter mouse cells but essentially lost the capacity to propagate in them. The neutralizing antibody-accessible determinants on HIX and HIX-RD resembled those of Moloney murine leukemia virus (M-MuLV) and, to a lesser extent, those of Friend or Rauscher MuLV and two murine xenotropic viruses (MuX). The entire *gag* region structural proteins of HIX appeared to be very similar or identical to those of M-MuLV. HIX and HIX-RD gp70 polypeptides were not mixtures of MuX and M-MuLV gp70's but exhibited type-specific determinants different from known MuLV's. Tryptic peptide maps of the gp70's of HIX-type viruses indicated that HIX virus is the product of recombination between ecotropic and xenotropic

viruses within the envelope gene. There appeared to be little if any HIX-specific complementary DNA sequences that were not a part of or closely related to M-MuLV RNA. (46 refs)

- 78-6885 Mammalian Retrovirus-associated RNase H Is Virus Coded.** (Eng) Lai, M. T. (Tumor Virology Lab., Salk Inst., San Diego, CA, 92112); Verma, I. M.; Tronick, S. R.; Aaronson, S. A. *J Virol* 27(3): 823-825; 1978.

The virus-coded nature of the RNase H activity of a temperature-sensitive Rauscher murine leukemia virus (R-MuLV) mutant with thermolabile polymerase activity (*ts29*) was studied. Both the DNA polymerase and RNase H activities of the mutant viral enzyme were two to three times more thermolabile than the corresponding activities from the wild-type R-MuLV. A wild-type (phenotypic) revertant of *ts29* was isolated in which the kinetics of heat inactivation of the DNA polymerase and RNase H were comparable to that of the wild-type viral reverse transcriptase. The restriction to infection by two other R-MuLV mutants (*ts17* and *ts19*, which are also defective in early postpenetration functions) did not appear to be associated with a measurable function of the viral enzyme. The thermolability of the RNase H associated with *ts29* reverse transcriptase demonstrates that this activity, as well as that of the DNA polymerase, is a product of the mammalian C-type viral genome. The two activities appear to be localized on the same polypeptide chain. (18 refs.)

- 78-6886 Characteristics of Cellular RNA in Viral Leukemia.** (Rus) Butenko, Z. A. (Inst. Problem Oncology, Kiev, USSR); Smirnova, I. A. *Vopr Onkol* 24(10): 18-23; 1978.

This study was designed as an attempt to evaluate characteristic features of polyadenylate rich (poly-A) sequences in RNA from Rauscher leukemia virus (RLV)-transformed cells. RNA specimens were isolated from the spleens of BALB/c mice inoculated with RLV and of leukemia-free BALB/c mice. There was no difference in content of cytoplasmic poly-A rich RNA between the leukemic and normal cells, while the content of nuclear poly-A rich RNA in leukemic cells was slightly greater than that in normal cells. Electrophoretic analysis of nuclear poly-A rich RNA showed the presence of additional 30-35 S fraction in leukemic cells, which was absent in normal cells. (29 refs)

- 78-6887 Biosynthesis of Rauscher Leukemia Viral Proteins.** (Eng) Arlinghaus, R. B. (Biology Dept., Univ. Texas System Cancer Center, M. D. Anderson Hosp. and Tumor Inst., Houston, TX, 77030); Jamjoom, G. A.; Arcement, L. J.; Naso, R. B.; Karshin, W. L. In: *Third Inter-*

national Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 293-309; 1977.

The synthesis of murine leukemia viral proteins was investigated by immune precipitation of ³⁵S-methionine pulse-labeled and chased cultures of Rauscher murine leukemia virus (RLV)-infected JLS-V16 cells. The RLV structural proteins were found to be synthesized in infected cells by way of high-mol-wt precursor polyproteins. In a working model for the biosynthesis of RLV proteins, Pr1a + b, Pr2a + b, and Pr3 [approx 200,000 daltons (200K), 90K, and 80K, respectively] are primary gene products derived by translation of 35S viral RNA. Pr3 arises by a translational control mechanism in which ribosomes detach from the 35S viral messenger RNA after translating Pr3. However, the ribosomes can proceed to translate the polymerase gene in 1/10-20 times to yield Pr1a + b. Pr1a + b thus is cleaved to form reverse transcriptase (RT)-specific proteins [Pr RT1 (145K), 2 (135K), and 3 (85K)] and, possibly, Pr3. Viral proteins p30, p15, p12, and p10 and RT are contained in Pr1a + b, gp69/71 and p12E are contained in Pr2a + b. Pr1b may be derived from Pr1a by proteolytic cleavage or some other posttranslational alteration. Pr2a and Pr2b are assumed to have the same core polypeptide that is glycosylated to different extents during or after translation to produce Pr2a or Pr2b. p30, p15, p12, and p10 are mainly generated by a series of cleavages of Pr3, producing Pr4, Pr5, and Pr6 (65K, 55K, and 45K) in that order. p10 is produced by cleavage of Pr4 to Pr5, p15 by cleavage of Pr5 to Pr6, and p30 and p12 by cleavage of Pr6. Treatment of infected cells with a proteolytic enzyme inhibitor such as tolylsulfonylphenylalanyl chloromethyl ketone caused a build-up of Pr1a + b and prevented the formation of mature structural proteins and RT. The main feature of this model is that a translational control mechanism exists that results in synthesis of a much lower amount of RT than viral structural proteins. (33 refs)

- 78-6888 Inhibition by RNA of RNase H Activity Associated with Reverse Transcriptase in Rauscher Murine Leukemia Virus Cores.** (Eng) Sarngadharan, M. G. (Dept. Cell Biology, Litton Bionetics, Inc., Bethesda, MD, 20014); Kalyanaraman, V. S.; Gallo, R. C. *J Virol* 27(3): 568-575; 1978.

Virion cores of Rauscher murine leukemia virus (R-MuLV) were examined to determine if the absence of detectable RNase H activity in these fractions was a result of some selective inhibition. Earlier findings that R-MuLV cores, when isolated by a density gradient, show no detectable RNase H activity were confirmed. The absence of RNase H activity in the core fractions was shown to be due to a selective inhibition of this activity by viral RNA. Direct evidence that viral RNA-mediated inhibition of the RNase H activity was the

cause of the apparent absence of RNase H activity in the isolated core fraction was obtained by studying the effect of viral and other RNAs on RNase H purified from isolated viral cores. Irrespective of the substrate used for measurement, the enzyme was generally inhibited by a variety of natural and synthetic RNAs. Although viral RNA was a strong inhibitor, polyguanylic acid was by far the most potent inhibitor of the reverse transcriptase-associated RNase H. The RNase H activity associated with a highly purified preparation of simian sarcoma virus reverse transcriptase was also similarly inhibited by RNA, suggesting that this property may be general for mammalian RNA tumor viruses. A rabbit anti-reverse transcriptase IgG inhibited both the reverse transcriptase and RNase H activities of the enzyme purified from cores. Overall, the results are consistent with the idea that RNase H and reverse transcriptase are two activities present on the same protein molecule. (21 refs.)

78-6889 A Study of the Synthesis and Processing of Rauscher Leukemia Virus-specific Polypeptides in Infected Cells and Their Assembly into Virus Particles. (Eng) Jamjoom, G. A. (Univ. Texas Health Science Center, Houston Graduate Sch. Biomedical Sciences, Houston, TX). *Diss Abstr Int [B]* 39(2): 666; 1978. (no refs)

78-6890 Physical Association of Murine Leukemia Virus Envelope Glycoprotein and Mouse Major Histocompatibility Antigens on Leukemia Cell Surfaces and their Recognition as Target Antigens by Cytotoxic T-Lymphocytes (Meeting Abstract). (Eng) Zarling, D. A. (Univ. Wisconsin, Madison, WI, 53706); Watson, A.; Duke, R. E.; Keshet, I.; Bach, F. H. *J Cell Biol* 79(2, part 2): 401a; 1978. (no refs)

78-6891 Persistence of Sindbis Virus in Oncornavirus-producing Cultures. (Rus) Pogodina, V. V. (Inst. Poliomyelitis and Viral Encephalitis, Moscow, USSR); Fokina, G. I.; Kiseleva, L. L.; Graevskaia, N. A.; Sito, A. F.; Ivanov, A. P. *Vopr Virusol* (2): 196-201; 1978.

Two continuous cell lines (PKR-1 and PKR-2) were derived from a primary culture of BALB/c embryo cells infected with Rauscher leukemia virus (RLV). PKR-1 and PKR-2 were infected with Sindbis virus (SV) and/or repeatedly infected with RLV. The cultures, maintained for 18 mo, retained their ability to produce C-type oncornavirus. Marked reverse transcriptase activity was detected in line PKR-1 from passages 19 to 68 and in PKR-2 from passages 26 to 70. The lines contained the murine oncornavirus-specific antigen gs-1. Characteristic features of SV persistence were development of homologous interference with SV without interferon participation and progressive repression of arbor virus and oncornavirus function. (8 refs)

78-6892 B-MuX: A Unique Murine C-type Virus Containing the "env" Gene of Xenotropic Viruses and the "gag" Gene of the Ecotropic Virus. (Eng) Ihle, J. N. (Cancer Biology Program, NCI Frederick Cancer Res. Center, Frederick, MD, 21501); Fischinger, P.; Bolognesi, D.; Elder, J.; Gautsch, J. W. *Virology* 90(2): 255-264; 1978.

A unique xenotropiclike virus (B-MuX) isolated by clonal purification from iododeoxyuridine-induced Kirsten sarcoma virus-transformed BALB/c nonproducer cells was characterized. B-MuX had the host-range properties of other murine C-type xenotropic viruses. It reciprocally shared interference properties with BALB:virus-2 (BALB-1), and the neutralization spectra suggested that the two viruses had very similar, if not identical, neutralizing antibody-eliciting determinants on their gp70 polypeptides. B-MuX contained an *env* gene similar to that of the endogenous BALB-2 xenotropic virus and *gag* gene products similar to those of the endogenous ecotropic virus. The p30 of B-MuX was structurally similar to that of the endogenous ecotropic virus and differed from the p30 of the BALB/c xenotropic virus, as determined by tryptic peptide analysis. The results suggest that B-MuX is a new type of endogenous xenotropic virus or a recombinant between the endogenous xenotropic and ecotropic viruses. The *gag* gene region does not contribute to this virological property. (34 refs)

78-6893 Surface Morphology of Normal and Virus-transformed Cells In Vitro. (Rus) Samil'chuk, E. I. (Lab. Experimental Oncology, Inst. Experimental Pathology and Therapy, Acad. Medical Sciences, USSR, Sukhumi, USSR); Timanovskaia, V. V.; Kukava, G. G. *Tsitologiia* 20(10): 1205-1208; 1978.

The morphology of the mink lung cell line Mv1Lu and its Kirsten sarcoma virus-transformed counterpart, Ki-Mv1Lu, was studied in vitro. In monolayer culture, the morphology of the normal cells differed sharply from that of the transformed cells. The Mv1Lu monolayer consisted of uniform, flat, polygonal cells with surface microvilli. At low cell density, foci of dense growth consisting of cells morphologically identical to those of the monolayer were seen. The transformed cells were characterized by morphological heterogeneity; the cells were polygonal, flat, spherical, and spindle-shaped. Microvilli, blebs, and filopodia were seen on the surface. The morphology of the Ki-Mv1Lu cells was independent of cell density. There was, however, nothing in the cell-surface morphology that was absolutely specific for the transformed cells. (10 refs)

78-6894 Comparison of the Genomic Organization of Kirsten and Harvey Sarcoma Viruses. (Eng) Shih, T. Y. (Lab. Tumor Virus Genetics, NCI, Bethesda, MD, 20014); Williams, D. R.; Weeks, M. O.; Maryak, J. M.; Vass, W. C.; Scolnick, E. M. *J Virol* 27(1): 45-55; 1978.

The genomic RNA's of Kirsten murine sarcoma virus (Ki-MuSV), Harvey murine sarcoma virus (Ha-MuSV), and the replication-defective endogenous rat virus were compared, and their structure and function were correlated. Genome organization and sequence homology were studied by fingerprinting large RNase T1-resistant oligonucleotides (ON) and by cross-protecting homologous ON against RNase A and T1 digestion with complementary DNA (cDNA) prepared from each of the other viral RNA's. Ki-MuSV and Ha-MuSV RNA shared a series of rat-derived ON beginning approx 1 kilobase (kb) from the 3' end and extending to within 1.5 kb at the 5' end of Ki-MuSV RNA. The total map distance covered was about 5.5 kb. The eight ON covering the 1.5 kb assigned to the 5' end of Ki-MuSV RNA were not found in Ha-MuSV RNA. However, by protection of Ki-MuSV RNA with cDNA from the rat virus, 5/8 ON could be designated as rat genetic information. Since Ha-MuSV is approx 6.5 kb and Ki-MuSV is 8.0 kb in size, the major difference between them is the 1.5 kb at the 5' end of Ki-MuSV RNA not present in Ha-MuSV RNA. When the viral RNA's were translated in vitro in cell-free systems, Ki-MuSV yielded a major product of 50,000 daltons, Ha-MuSV RNA a major product of 22,000 daltons. These polypeptides are clearly distinguishable from each other upon tryptic mapping and apparently are translated from the full-genome-length viral RNA, suggesting that they are products of the 5' portions of the viral RNA. They may provide the necessary protein markers for identifying in vivo virus-coded proteins. (23 refs)

78-6895 In Vitro Isolation of Stable Rat Sarcoma Viruses. (Eng) Rasheed, S. (Dept. Pathology, Univ. Southern California Sch. Medicine, Los Angeles, CA, 90023); Gardner, M. B.; Huebner, R. J. *Proc Natl Acad Sci USA* 75(6): 2972-2976; 1978.

At low passage, a Sprague-Dawley (SD-1) rat embryo culture released an endogenous ecotropic C-type leukemia virus (SD-RaLV) and, after about 20 further passages, it underwent spontaneous transformation. The SD-RaLV released from the transformed cells did not cause rapid transformation of other rat embryo cells. However, when the transformed cells were cocultivated repeatedly with three different chemically transformed and serially transplanted rat tumor cell lines (4-nitroquinoline oxide-induced sarcoma, dimethylhydrazine-induced carcinoma, and N,N'-2,7-fluorenylene bis-2,2,2-trifluoroacetamide-induced hepatoma), rapidly fibroblast-transforming "sarcoma" viruses (RaSV) were recovered after each attempt. RaSV was not recovered from one of these tumor cell lines before transplantation, and focus-forming virus could not be rescued from these same tumor cells C-type by cocultivation with other cells releasing heterologous C-type viruses. Foci were induced on normal rat kidney (NRK) and several other rat embryo cell strains within 7-15 days, and both productive and nonproductive NRK clones were derived. The productive clones were positive for rat-specific p30 antigen and the RaSVs released were

serially transmitted to other rat embryo cells. RaSV genome was rescued from the nonproductive clones by superinfection with SD-RaLV, wild rat C-type virus, and several heterologous C-type viruses. It is concluded that naturally occurring transformation-specific (*src*) genes are being recovered in vitro in the form of stable sarcoma viruses from cells into which no sarcoma virus had apparently been introduced. The viruses differ from the Kirsten and Harvey strains of murine sarcoma virus in that they apparently contain no murine leukemia virus sequences and are of purely rat origin. (41 refs)

78-6896 Characterisation of a Tumor-Specific Antigen on the Surface of Feline Lymphosarcoma Cells. (Eng) Snyder, H. W. (Lab. Viral Oncology and Veterinary Oncology, Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Hardy, W. D.; Zuckerman, E. E.; Fleissner, E. *Nature* 275(5681): 656-658; 1978.

A 70,000-mol-wt protein that exhibited antigenic determinants in common with the feline oncornavirus-associated cell membrane antigen (FOCMA) was identified on the surface of feline lymphosarcoma (LSA) cells and cultured transformed feline lymphoblastoid cells. Cell surface molecules carrying FOCMA determinants were characterized by enzymatic radioiodination of viable cells, precipitation with typing serum from detergent lysates, and analysis of proteins in immunoprecipitates by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). In LSA cells, viral antibodies in FOCMA typing serum always precipitated a single protein species, regardless of whether the cell showed concomitant expression of feline leukemia virus (FeLV) structural antigens. In contrast, immunoprecipitation of FeLV gp70 molecules with FeLV-neutralizing serum was restricted to FeLV-positive cells. Absorption experiments proved that the 70,000-mol-wt FOCMA molecule in LSA cells was serologically distinguishable from surface antigens related to FeLV structural proteins. FOCMA-carrying FeSV-transformed nonproducer mink cells gave two protein species approx 85,000 and 65,000 mol-wt upon SDS-PAGE after precipitation by FOCMA antiserum. (18 refs)

78-6897 The Retrovirus Particles in Human Myeloma Cells RPMI8226: Morphological, Biochemical, Immunological and Infective Transmission Studies. (Eng) Grofova, M. (Cancer Res. Inst., Slovak Acad. Sciences, 88 32 Bratislava, Czechoslovakia); Popovic, M.; Ogura, H.; Matoska, J.; Lizonova, A.; Nilsson, K.; Kuzela, S. *Neoplasma* 25(4): 423-437; 1978.

The morphological, biochemical, and immunological properties of a retrovirus (RPMI8226V) isolated from RPMI8226 human myeloma cells were investigated, and propagation of the virus in various animal and human cells was studied. Ultrastructural observations revealed that RPMI8226V particles have a C-type morphology. They were classified into

three categories: immature and mature particles indistinguishable from typical C-type mammalian oncornaviruses and typical C-type particles with an intermediate membrane. Budding particles in secondarily infected human neoplastic cells contained doughnut-shaped nucleoids characteristic of C-type particles. ³H-uridine-labeled RPMI8226V particles had a buoyant density of 1.17 g/ml in a sucrose gradient containing high mol wt RNA, and the distribution of viral structural proteins upon sodium dodecyl sulfate-polyacrylamide gel electrophoresis was characteristic of that of oncornaviruses. The mol wt of the internal structural proteins ranged from 10,000 to 30,000 daltons. The virus contained an Mg-dependent reverse transcriptase (RT). The cellular homogenate and ultracentrifugate from RPMI8226 cultures did not react with antibodies against murine leukemia virus, feline leukemia virus, RD114, Mason-Pfizer monkey virus, simian sarcoma virus, and avian leukemia/sarcoma virus. The only reaction occurred with anti-bovine leukemia virus (BLV) antibodies. However, anti-BLV serum inhibiting the RT activity of BLV to 60% did not cross-react with the RT of RPMI8226V. In contrast to BLV concentrates, neither XC or KC cells showed syncytia formation by RPMI8226V. RPMI8226V replication was restricted to human tumor and normal human glialike cells. The data indicate that RPMI8226V may be of bovine origin. (40 refs)

78-6898 Induction of Deoxythymidine Kinase Activity in Several Mammalian Cell Lines after Infection with Six Different Strains of Equine Herpesvirus Type 1 (EHV-1). (Eng) Allen, G. P. (Dept. Microbiology, Univ. Mississippi Medical Center, Jackson, MS, 39216); McGowan, J.; Bryans, J. T.; Randall, C. C.; Gentry, G. A. *Virology* 90(2): 51-359; 1978.

The ability of six strains of equine herpesvirus type 1 (EHV-1) to induce deoxythymidine kinase (dTK) activities in mouse 3T3 cells, horse embryo fibroblasts (KyED), equine transitional cell carcinoma cells (HT), and owl monkey kidney cells (OMK) was studied. Increased deoxythymidine triphosphate (dTTP)-resistant dTK activity was observed after infection of all cell types with any of the six strains of EHV-1. Increased levels of dTTP-resistant dTK were also detected in liver homogenates derived from Syrian hamsters infected with EHV-1. This activity appeared to be virus-coded. EHV-1 appeared to induce a dTK activity in HT and KyED cells that comigrated in polyacrylamide gels with the cytosol dTK of the host cell. Replication of wild-type EHV-1 in 3T3 cells was inhibited by arabinosylthymine (ara-T), but replication of the virus in OMK, HT, and KyED cells was considerably more resistant to inhibition by ara-T. The data indicate that infection of cells with any strain of EHV-1 results in the induction of a new, virus-coded dTK activity. (40 refs)

78-6899 Transformation of Warts to Malignancy in Alimentary Carcinoma in Cattle. (Eng) Jarrett, W.

F. (Dept. Veterinary Pathology, Univ. Glasgow, Bearsden Road, Glasgow G61 1QH, Scotland). *Bull Cancer (Paris)* 65(2): 191-194; 1978.

The naturally occurring high incidence of alimentary carcinoma in beef cattle in the highland areas of Britain offers an excellent opportunity to study the interactions between a papilloma virus and an environmental chemical, possibly derived from bracken fern, that has putative mutagenic and immunosuppressive properties. This development of carcinoma is associated with the presence of bracken fern on high-incidence farms, and many of the carcinomas arise in preexisting virus-induced papillomas. Papillomas are much commoner and occur in greater numbers in animals of all ages on the cancer farms than in cattle on lowland farms. Carcinomas have only been seen in cattle >6 yr old. The virus has been isolated, visualized, and purified; it produces papillomas when inoculated into the alimentary tract and skin. A total of 165 carcinomas were found in 80 cows with squamous carcinoma of the alimentary tract. They were distributed as follows: palate 4%, pharynx 8%, tongue 7%, esophagus and groove 41%, and rumen 30%. Papillomas or warts of the squamous epithelium lining the upper alimentary tract were found in 96% of these cows. There was a range of tumors from benign papillomas to papillomas with areas of malignant transformation to frank ulcerating and invasive carcinoma. (5 refs)

78-6900 Some Physical Properties of a Human Laryngeal Papillomavirus. (Ger) Liebermann, H. (Friedrich-Loeffler-Institut für Tierseuchenforschung, DDR-2201 Insel Riems, über Greifswald, E. Germany); Solisch, P.; Hahnefeld, H. *Arch Geschwulstforsch* 48(6): 552-558; 1978.

Ultracentrifugation of a human laryngeal papillomavirus produced particles sedimenting at 130S and 214S. Electron microscopy revealed the presence of 37-nanometer (nm) and 49-nm particles, with the latter having a buoyant density in CsCl gradients of 1.34 g/ml. This virus resembles a polyoma virus. (19 refs)

78-6901 In Vitro Transcription of Polyoma DNA. (Eng) Monjardino, J. (Div. Cell Studies, Royal Free Hosp. Sch. Medicine, 8 Hunter St., London WC1N 1BP, England); James, A. *Biochem Biophys Res Commun* 84(3): 618-626; 1978.

In vitro transcription of supercoiled DNA from nondefective polyoma virus (PV) by *Escherichia coli* RNA polymerase was successfully carried out, and the resulting complementary RNA (cRNA) was seen to be double stranded to a large extent, longer than the coding strand, and initiated from a limited number of sites. The incubation mixture for RNA synthesis contained 20 µg/ml PV DNA I, 75 µg/ml *E. coli*

RNA polymerase, and nucleotides including ^3H -GTP (0.15 Ci/millimole). Results of chromatographic separation of the double-stranded RNA product on CF11 cellulose and pancreatic RNA digestion, followed by cRNA annealing, proved that the transcription was at least partially symmetric. Electron microscope visualization of the transcription complexes showed long RNA chains up to 3x the length of the template strand. In the presence of rifampicin, transcription was usually initiated from 2-3 initiation sites, proceeding at a rate of 16 nucleotides/sec under suboptimal conditions. When 32 transcription complexes were lined up on linear DNA molecules, it was evident that the RNA could not have originated from a common initiation site. Further, cRNA chains in some complexes differed in length by more than a transcript of the entire DNA template. These findings support the hypothesis that transcription took place from both DNA strands. (16 refs)

78-6902 Expression of Polyoma Virus In Heterokaryons Between Embryonal Carcinoma Cells and Differentiated Cells. (Eng) Boccara, M. (Departement de Biologie Moleculaire, Institut Pasteur, 25 rue du Dr. Roux, 75015 Paris, France); Kelly, F. *Virology* 90(1): 147-150; 1978.

Polyoma virus (PV)-resistant PCC3/A/1 embryonal carcinoma cells were fused with two types of susceptible cells: differentiated teratoma-derived PCD3 cells, which are fully permissive for PV, and BHK21 cells, which can express only the early viral genes. Cells from one parent were infected with 20 plaque forming units of PV, fused 4 hr later with the other ^3H -thymidine labeled parent using β -propiolactone-inactivated Sendai virus, and examined by autoradiography 48 hr post-infection for the presence of V antigen or radioactively labeled nuclei. When infected PCC3/A/1 cells were fused with PCD3 cells, 20% of the heterokaryons were V antigen-positive. Both parent cells were necessary for viral expression, suggesting that the virus entered the PCC3/A/1 cells but was expressed only upon fusion with permissive cells. Fusion of infected PCD3 cells with PCC3/A/1 cells resulted in 60% antigen-positive heterokaryons, a percentage comparable to that of infected PCD3 homokaryons or isolated PCD3 cells. Nonpermissive preinfected BHK21 cells produced 5% antigen-positive heterokaryons when fused with PCC3/A/1 cells, compared with no apparent staining in unfused, infected BHK21 cells or BHK21 homokaryons. These experiments indicate that blocked response to PV in pluripotent teratocarcinoma cells occurs after penetration of the viral particle but before the synthesis of the T antigen, and that susceptibility to infection in the differentiated cells is dominant over resistance in the embryonal carcinoma cells. (10 refs)

78-6903 Isolation of Polyoma Viruses Lacking Endonuclease *Hind*III Sites. (Eng) Anderson, D. M. (Roche Inst. Molecular Biology, Nutley, NJ, 07110); Bendig, M. M.; Folk, W. R. *Virology* 89(2): 637-642; 1978.

Spontaneous mutants of polyoma virus that have specific alterations at one of two endonuclease *Hind*III sites in the polyoma genome (one in the early region, the other in the late region) were isolated and partially characterized. The viruses were divided into two groups on the basis of their genome structure and complementation requirements: Group I viruses did not require complementing genomes in order to form plaques, but Group II viruses did. Infection by group I viruses produced homogeneous populations of DNA, but infection by Group II viruses always produced two DNA species, regardless of the number of attempts to plaque-purify them. In almost every instance, a DNA without one *Hind*III site was accompanied by a DNA having an alteration at the other *Hind*III site. Many of the viruses in both groups synthesized viral DNA at 32 and 39 C, although several Group II mutants did not synthesize form I DNA as well at 39 C as at 32 C, indicating thermolability of early gene products. Several of these mutants will be useful in probing the function of the polyoma genome. Group I mutants may express altered early functions. In addition, most of these viruses are capable of proceeding through a normal lytic infection and may therefore, be more useful as cloning vehicles than wild-type polyoma DNA. Group II mutants, altered in the early or late region, are difficult to grow in large amounts, and the individual species of the pairs of mutants must be separated before the extent and effects of the alterations can be defined. (28 refs)

78-6904 Polyoma Virus High Molecular Weight Nuclear RNA Codes for Capsid Protein VP2 In Vitro. (Eng) Kamen, R. I. (Transcription Lab., Imperial Cancer Res. Fund, London WC2A 3PX, England); Wheeler, T. Smith, A. E. *Virology* 89(2): 461-474; 1978.

An attempt was made to determine whether polyoma virus (Py) nuclear RNA molecules, which contain messenger RNA-like sequences but which are assumed not yet extensively spliced, can direct the synthesis of viral proteins in vitro. RNA extracted from the nuclei of 3T6 mouse cells late after infection by Py was translated in vitro to give one predominant polypeptide. This polypeptide was identified as virion protein VP2 by polyacrylamide gel electrophoresis, specific immunoprecipitation, and tryptic peptide analysis. The active nuclear RNA species sedimented between 15S and 50S on sucrose gradients after denaturation. The bulk of the active viral nuclear RNA did not bind to oligo(dT)-cellulose and synthesis of Py VP2 was inhibited by m⁷Gp under conditions in which translation of Py-complementary RNA and EMC RNA are not inhibited. It is concluded that VP2 coding activity is not only a function of mature cytoplasmic 19S RNA, but also of Py nuclear RNA, which is probably capped but not polyadenylated. Determination of the size of the active RNA molecules indicated that all size classes of nuclear RNA have VP2 coding activity and that this activity is unlikely to result from contamination of the high mol wt RNA with aggregated 19S RNA. (49 refs)

6905 **Evaluation of Normal and Neoplastic Human Tissue for BK Virus.** (Eng) Israel, M. A. (Lab. Virology, Natl. Inst. Allergy and Infectious Diseases, Bethesda, MD, 20014); Martin, M. A.; Takemoto, K. K.; Wley, P. M.; Aaronson, S. A.; Solomon, D.; Khoury, G. *Virology* 90(2): 187-196; 1978.

The role of the human papovavirus BK virus (BKV) in human neoplasia was evaluated using nucleic acid hybridization and indirect immunofluorescence techniques. None of 12 normal organ preparations, 5 human tumors, or 16 human tumor cell lines was positive for sequences homologous to BKV DNA. Detectable levels of antibody specific for BKV (tumor)-antigen were not found in any of 55 human tumor cell lines or in serum samples from any of 67 cancer patients. On the basis of these findings, it is unlikely that BKV is commonly associated with human cancer. (37 refs)

6906 **Cell Surface Morphology and Adhesive Properties of Normal and Virally Transformed Cells Treated with Tunicamycin, an Inhibitor of Protein Glycosylation.** (Eng) Duksin, D. (Dept. Biochemistry, Biological Structure and Medicine, Univ. Washington, Seattle, WA, 98195); Holbrook, K.; Williams, K.; Bornstein, P. *Exp Cell Res* 116(1): 153-165; 1978.

The effects of tunicamycin (0.1 or 0.2 $\mu\text{g/ml}$) on the biochemical and functional surface properties of mouse 3T3 cells, simian virus 40-transformed 3T3 cells, and polyoma virus-transformed 3T3 cells were studied. The cells of all lines became rounded, leaving long attenuated cell processes attached to the substrate. In addition, the nontransformed 3T3 cells showed extensive ruffling of the cell surface and dilation and loss of ribosomes from the rough endoplasmic reticulum. There was a marked reduction in all cell lines in a cell surface protein that was similar or identical to fibronectin. Tunicamycin treatment also resulted in a reduction in the length of cell adhesion to the substrate, a decrease in plating efficiency, and a marked inhibition in the cell spreading rate on the surface of the tissue culture plate; the latter two changes were more pronounced in the transformed cells than the nontransformed cells. The data suggest that cell surface glycoproteins, including fibronectin, play a role in determining the surface morphology and adhesive properties of cells. (8 refs)

6907 **Mobility of Histones on the Chromosomes of Simian Virus 40.** (Eng) Beard, P. (Swiss Inst. Experimental Cancer Res., CH-1066 Epalinges, Switzerland). *Cell* 15(3): 955-967; 1978.

near simian virus 40 (SV40) chromosomes were prepared by *EcoRI* nuclease cleavage of the circular SV40 chromosomes released from virions with dithiothreitol at pH 9.8. Chromatin-DNA hybrids were constructed with segments of

^3H -labeled, naked SV40 DNA covalently joined via the *EcoRI*-generated cohesive ends to segments of linear SV40 chromosome. Upon incubation of chromatin-DNA hybrids at 37 C and moderate ionic strength, histones migrated onto the labeled DNA while retaining the nucleosome structure. This was shown by (1) the pattern of micrococcal nuclease digestion of labeled DNA, (2), by nitrocellulose filter binding of labeled DNA after redigestion of the chromatin-DNA hybrids with *EcoRI*, and (3), by examination of chromatin-DNA hybrids in the electron microscope. Migration was slow, being apparent after several hours. Parallel experiments in which naked DNA and chromosomes were mixed without joining showed no transfer of nucleosomal histone between DNA molecules. The kinetics of *EcoRI* cleavage of the DNA in virion-derived SV40 chromosomes are also consistent with the notion that nucleosomal histones, in the absence of other proteins, can move on DNA. (59 refs)

78-6908 **Influence of Agents Reducing Cell-Substrate Adhesion on Protein and Glycoprotein Patterns of Transformed Mouse Fibroblasts in Culture.** (Rus) Liubimov, A. V. (Lab. Mechanisms Carcinogenesis, Oncology Res. Center, Acad. Medical Sciences, USSR, Moscow, USSR). *Tsitologiya* 20(10): 1179-1185; 1978.

The effect of substances that reduce cell-substrate adhesion (trypsin, EDTA, and urea) on the protein and glycoprotein patterns of methylcholanthrene-transformed mouse fibroblasts (L cells), the serum-free derivative of L cells (LSF), and mouse fibroblasts transformed by simian virus 40 (M-22 cells) was studied by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. Incubation with trypsin (10-1,000 $\mu\text{g/ml}$ for 10 min at 37 C) caused no marked changes in the protein and glycoprotein patterns of L cells, but urea (1 mole, 2 hr) and EDTA (200 $\mu\text{g/ml}$, 2 hr) removed a protein with a mol wt of 240,000. In LSF, trypsin (10 $\mu\text{g/ml}$, 10 min, 37 C) reduced the level of a 271,000-dalton protein considerably. In M-22 cells, trypsin (1-1,000 $\mu\text{g/ml}$) caused a protein with a mol wt of 270,000 to disappear. Urea extracted a 270,000-dalton protein nearly completely and a 139,000-dalton protein considerably. EDTA had no marked effect on protein and glycoprotein patterns, but it removed a protein with a mol wt of 270,000. The findings suggest that deficient contact reactions of transformed cells may be due to changes in the pattern and properties of cell components that are sensitive to alterations of adhesion. (7 refs)

78-6909 **Augmented Immunogenicity of Tumor Cell Membranes Produced by Infection with Influenza Virus as Compared to Moloney Sarcoma Virus.** (Eng) Takeichi, N. (Lab. Pathology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo, Japan); Austin, F. C.; Oikawa, T.; Boone, C. W. *Cancer Res* 38(12): 4580-4584; 1978.

The immunogenicity of tumor cell membranes from Moloney

murine sarcoma virus (MSV)- and influenza virus-infected cells was tested. The tumor-associated transplantation antigens (TATA) of crude membrane extracts from simian virus 40 (SV40)-transformed BALB/3T3 tumor cells lytically infected with influenza virus were much more immunogenic than the TATA of extracts from uninfected cells, as measured by their ability to induce heightened resistance to tumor graft challenge or by heightened lymphocyte-mediated cytotoxicity against tumor cells in vitro. When intact tumor cells (as opposed to membrane extracts) were productively infected with MSV, they became so immunogenic they would only grow in x-irradiated syngeneic animals. However, crude membrane extracts from the MSV-infected tumor cells showed no increase in TATA activity analogous to that seen after infection with influenza virus. Thus, influenza virus augmentation of tumor membrane TATA may be different from the oncornavirus augmentation of intact tumor cell TATA reported previously. It appears that MSV and, possibly, other oncornaviruses cannot be used to augment the TATA activity of tumor cell membranes in the same way that other surface-budding viruses can. (25 refs)

- 78-6910 Simian Virus 40 A Gene Function: DNA Content Analysis of Chinese Hamster Cells Transformed by an Early Temperature-sensitive Virus Mutant.** (Eng) Robinson, C. C. (Dept. Pathology, Univ. Colorado Medical Center, 4200 E. Ninth Ave., Denver, CO, 80262); Lehman, J. M. *Proc Natl Acad Sci USA* 75(9): 4389-4393; 1978.

Replication of Chinese hamster embryo cell lines (ChH WT-2, ChH A58, and ChH A58-1) transformed by wild-type simian virus 40 (WT SV40) and the SV40 temperature-sensitive A gene mutant (*tsA58*) was examined by flow microfluorometry and autoradiography of ³H-thymidine-labeled cells to determine whether DNA synthesis in transformed cells is initiated by the A gene. At the permissive temperature (37 C), the *tsA58*-transformed cells resembled the WT transformants in cell morphology, colony formation, high saturation density, and rapid replication. They seemed to revert to a normal phenotype at the nonpermissive temperature (40.5 C). However, flow microfluorometric analysis of the cell DNA content at 40.5 C showed that under conditions in which normal embryo cells enter a resting state, the *tsA58* transformants continued to replicate. The low density of the cultures was maintained by a balance among cell proliferation, cell death, and sloughing of dead cells into the culture medium, and it did not represent a return to normal growth. Thus, loss of the phenotypic characteristics of transformation cannot be explained by arrest of the cells in the G₁ (G₀) phase of the cell cycle. It is suggested that the initiator hypothesis for the function of the A gene product in the maintenance of transformation must be reevaluated. (34 refs)

- 78-6911 Suppressive Effects on Simian Virus 40-induced Oncogenesis of Several Immunosuppressive**

Agents and Hormonal Modifications Applied During the Latent Period. (Eng) Ohtaki, S. (Dept. Pathology, Nalt. Inst. Health, Tokyo Gakuen 4-7-1, Musashi-Murayama, Tokyo 190-12, Japan). *Cancer Res* 38(12): 4698-4710; 1978.

Host factors affecting tumorigenesis at different stages, especially before and after the appearance of tumor cells, were studied in two experiments: (1) simian virus 40 (SV40)-induced oncogenesis in Syrian golden hamsters, to investigate the latent period; and (2) transplantation of homologous, primary SV40 tumor cells into hamster, to investigate a late stage of tumorigenesis. The mean latent period for SV40 tumor induction was about 6 wk shorter in female hamsters than in males ($p < 0.02$). The mean latent period in castrated females was 12.6 wk longer than that in intact females. In contrast, tumor development was not significantly affected by orchietomy. Estrone treatment (0.2-0.3 mg, sc) at birth delayed tumor development significantly in both sexes. Tumor development was significantly accelerated by testosterone treatment (0.5 mg, sc) of males at age 15 wk, the mean latency period being decreased by 11 wk. By each of these hormonal modifications, growth of transplanted SV40 tumors was influenced in a different way from that of tumor induction. Immunosuppressive treatments, such as thymectomy or administration of antilymphocyte sera, cyclophosphamide, or cortisone acetate, delayed and decreased tumor development when applied in the latent period, and the degree or pattern of this effect varied from one procedure to another, depending on the sex and age of the animals. In contrast, tumor growth was markedly accelerated in thymectomized or cortisone-treated hosts of either sex. The different and almost reverse effect of the same procedures in the two phases of tumorigenesis indicates that two distinct mechanisms may be operating during these phases. The different effect may be due to the absence of "mature" neoplastic cells in the latent period, except for a few weeks before the appearance of a palpable tumor. These results suggest that the latent period may be needed for completion of SV40-induced neoplastic conversion of cells. (47 refs)

- 78-6912 Simian Virus 40 Production After Viral Uncoating in the CV-1 Cell Nucleus.** (Eng) Gershey, L. (Rockefeller Univ., New York, NY, 10021); Diacumakos, E. G. *J Virol* 28(1): 415-416; 1978.

A normal yield of infectious simian virus 40 was produced by a culture of African green monkey kidney CV-1 cells after a few cells were inoculated with an av of one particle of plaque-purified virus per nucleus by microinjection. (7 refs)

- 78-6913 Simian Virus 40 DNA Replication in Isolated Replicating Viral Chromosomes.** (Eng) Su, R. (Dept. Microbiology, Univ. Kansas, Lawrence, KS, 66044); DePamphilis, M. L. *J Virol* 28(1): 53-65; 1978.

Three soluble subnuclear systems (nuclear extracts, nucle-

protein complexes, and replicating chromosomes prepared from simian virus 40-infected CV-1 cells) were studied to determine the minimum conditions necessary for DNA replication in vitro. DNA synthesis was measured with and without CV-1 cell cytosol in the reaction mixture. With nuclear extracts, cytosol stimulated total DNA synthesis (2-3 times), elongation of nascent DNA chains, maturation and joining of Okazaki pieces (transient intermediates), and the conversion of replicating viral DNA into covalently closed, superhelical DNA. The response of nucleoprotein complexes was similar but often 10%-30% lower. In contrast, isolated replicating chromosomes in the presence of cytosol appeared only to complete and join Okazaki pieces on the DNA templates. They failed to extend nascent DNA chains prelabeled in vivo with ^3H -thymidine or labeled in vitro with α - ^{32}P -deoxycytosine triphosphates (α - ^{32}P -dCTP). Consequently, the conversion of viral replicating DNA into mature DNA was given to eight times less than that observed in nuclear extracts. In the absence of cytosol, Okazaki pieces were still labeled with α - ^{32}P -dCTP in vitro, but completely failed to join the growing nascent DNA chains, demonstrating the requirement of cytosol factors at this stage in DNA elongation. Treatment of nucleoprotein complexes with 0.6-2.0 M NaCl resulted in complete loss of endogenous DNA synthesis and lack of response to cytosol. These results demonstrate that continuation of endogenous DNA replication in vitro requires both the soluble cytosol fraction and a complex nucleoprotein template whose ability to continue DNA synthesis depends on its concentration and ionic environment during its preparation. (31 refs)

78-6914 Non-Coordinate Expression of SV40 Transformation in Cell Hybrids (Meeting Abstract). (Eng) Howell, N. (Sidney Farber Cancer Inst., Boston, MA, 02115); Sager, R. *J Cell Biol* 79(2, part 2): 396a; 1978. (no refs)

78-6915 SV40-transformed Hamster Cells Resistant to 100-250 $\mu\text{g}/\text{ml}$ of Ethidium Bromide. (Eng) Volf, G. (Max-Planck-Institut für Virusforschung, 7400 Tübingen, W. Germany); Tejmar, L.; Borell, S.; Klietmann, W. *Cell Sci* 33: 157-169; 1978.

Simian virus 40 (SV40)-transformed hamster cells selected for resistance to ethidium bromide (EB, 100-250 $\mu\text{g}/\text{ml}$) were characterized. EB resistance was maintained during propagation in EB-containing medium and thus seemed to be genetically determined. The EB-resistant cells were considerably less tumorigenic in Syrian golden hamsters than wild-type cells. They had a normal ultrastructure, except for a highly condensed conformation of the mitochondrial cristae. Unlike wild-type cells, the resistant cells showed no significant inhibition of mitochondrial DNA synthesis in the presence of 16 $\mu\text{g}/\text{ml}$ EB. The polypeptides of the mitochondrial fractions of wild-type and resistant cells were significantly different:

polypeptide 14, which was present in wild-type cells, was absent or greatly reduced in the mitochondria of the resistant cells, and the relative proportions of polypeptides 1:2 and 7:8:9 were different. The mechanism of EB resistance in mammalian cells has not been determined. (27 refs)

78-6916 Simian Virus 40 T Antigen Binds to Host Cell Chromosomes. (Eng) D'Alisa, R. M. (Rockefeller Univ., New York, NY, 10021); Gershey, E. L. *Nature* 274(5667): 164-166; 1978.

The binding of simian virus 40 (SV40) T antigen to mammalian chromosomes was studied using a fibroblastic cell strain derived from a male Indian deer, *Muntiacus muntjak*, an animal with only seven chromosomes, which can be unequivocally identified. Cultured muntjac cells were infected with SV40 strain VA 4554 at multiplicities between 200 and 500 plaque-forming units/cell. Seventy-two hours after infection, the chromosomes were swollen in 0.075 M KCl for 12 min, fixed in 3:1 methanol:acetic acid, air-dried, and stained for T antigen by indirect immunofluorescence. The preparations were photographed on an inverted microscope. Alternatively, cells were grown in glass slides and arrested with colcemid before KCl treatment and fixation. No differences in chromosome morphology were detected with the two methods. T antigen was associated with all chromosomes, including the small Y, of infected cells. The binding appeared to be specific for the fluorescent chromosomes of infected cells, since uninfected cells did not contain fluorescent chromosomes and (2) presumably uninfected cells within the SV40-treated population also did not fluoresce. The similarity of the T-antigen binding patterns to Q- and G-banding patterns suggests that the antigen binds to initiation sites for host cell DNA replication. (27 refs)

78-6917 Definition of the Boundaries of the Origin of DNA Replication in Simian Virus 40. (Eng) Subramanian, K. N. (Dept. Microbiology, Univ. Illinois Medical Center, Chicago, IL, 60612); Shenk, T. *Nucleic Acids Res* 5(10): 3635-3642; 1978.

Using DNA sequencing techniques, the exact location of the deletion in *dl* 892, a viable deletion mutant of simian virus 40 (SV40) reported to map very near the unique replication origin of SV40, was determined. Autoradiographic studies showed that *dl* 892 lacks a segment of 19 nucleotides (located between positions 187 and 205 in the *Eco* RII-G sequence, both inclusive) present in wild-type SV40 DNA. In view of the fact that segments of DNA occurring distal position 186 could be deleted without affecting the replication of the viral DNA (and the ability of the virus to grow without a helper), one of the boundaries for the replication origin located distal to the *Hind* (11 + 111) -A-C junction could be placed at position 186. Previous studies indicate that sequences to the left of map position 0.660 are not needed for initiation of

SV40 DNA replication. Therefore, the other boundary of the replication origin has been placed at map position 0.660 corresponding to the *Hae* III restriction site at nucleotide 102 in the *Eco* RII-G sequence. Thus, according to the present estimate, the SV40 replication origin consists of a max of 85 nucleotides located between positions 102 and 185 in the sequence of the *Eco* RII-G fragment derived previously. This sequence includes the 27-nucleotide perfect palindrome, the 17-nucleotide "true" palindrome (containing a single imperfection in its sequence), the 17-nucleotide A-T-rich sequence, and the 15-nucleotide imperfect palindrome, all shown to be present in the previously derived *Eco* RII-G sequence. These and previous results have enabled the boundaries of the replication origin to be narrowed down to 85 nucleotides within the sequence of SV40. (10 refs)

78-6918 The Detection and Characterization of Multiple Forms of SV40 Nucleoprotein Complexes.

(Eng) Garber, E. A. (Dept. Biochemical Sciences, Princeton Univ., Princeton, NJ, 08540); Seidman, M. M.; Levine, A. J. *Virology* 90(2): 305-316; 1978.

Using a newly developed method for extracting multiple forms of simian virus 40 (SV40) nucleoprotein complexes from the nuclei of virus-infected cells, the production and maturation of the SV40 chromosome in vivo were studied. Four different forms of SV40 DNA-protein complexes were identified: a heterogeneous (75S to 200S) replicative intermediate; a 75S minichromosome; a 200S previrion particle; and a mature virion (250S). After replicating in the heterogeneous 75S to 200S complexes, the newly replicating chromosome appeared to be converted to the 75S form, which matured into the 200S previrion structure. By 45 to 60 min, mature virions were observed. The sequence of appearance of these complexes was suggestive of a precursor-product relationship. The data demonstrated that 90% of the viral DNA was encapsulated by 4 hr after its synthesis. (25 refs)

78-6919 Identification of Oncogenic Chromosomes in Transformed Human Cells. (Eng) Croce, C. M.

(Wistar Inst. Anatomy and Biology, 36th and Spruce Sts., Philadelphia, PA, 19104). In: *Neoplastic Transformation: Mechanisms and Consequences. Proceedings of a meeting held by the Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences in Berlin, May 9-13, 1977.* Dahlem Workshop on Neoplastic Transformation: Mechanisms and Consequences (Berlin, W. Germany): 314 pp.; 69-85; 1977.

To determine whether viral DNA sequences are associated with specific chromosomes in transformed cells and whether integrated viral DNA sequences are responsible for expression of the transformed phenotype and malignancy, a large number of somatic cell hybrids between rodent cells and dif-

ferent simian virus 40 (SV40)-transformed human cells were produced and investigated. Three independent SV40 T-antigen-positive hybrid clones between CT1D mouse cells and LN-SV SV40-transformed human cells were subcloned, and the subclones were analyzed for the expression of SV40 tumor antigen and the presence or absence of human chromosomes 7. Somatic cell hybrids between thymidine kinase-deficient IT-22 mouse or A3 hamster cells and GN54VA transformed human fibroblasts were also studied. The results showed that the SV40 genome can be integrated in at least two different human chromosomes: 7 and 17. These and further studies demonstrated that it was possible to map the integration sites of oncogenic viruses in virus-transformed human cells and to identify the human chromosomes responsible for the expression of malignancy by somatic cell hybridization. Since these chromosomes can be isolated on a normal inbred mouse strain background, it should also be possible to elicit humoral and cellular immunoresponses to human tumor-associated antigens using hybrid cells. (26 refs)

78-6920 The Sequences between 0.59 and 0.54 Map Units on SV40 DNA Code for the Unique Function of Small t Antigen. (Eng) Paucha, E. (Translation Lab Imperial Cancer Res. Fund, London WC2A 3PX, England); Smith, A. E. *Cell* 15(3): 1011-1020; 1978.

The hypothesis that the carboxy terminal portion of simian virus 40 (SV40) small t antigen is encoded by a sequence of nucleotides from the region between 0.59-0.54 map units on SV40 DNA was tested by characterizing the putative shortened forms or fragments of small t produced by SV40 mutants (dl 884, dl 885, dl 890) with deletions in this genomic region. Attempts to isolate the putative fragments of small t from mutant-infected cells, or from cell-free systems primed with messenger RNA (mRNA) from mutant-infected cells, resulted in only low yields of the fragments. Experiments using purified SV40 mRNA in low background cell-free systems, in which large T and small t could be detected without immunoprecipitation, suggested that these low yields were due to the reduced amounts of mRNA coding for the shortened forms of small t present in the mutant-infected cells. Larger amounts of putative fragments of small t were produced by translation of deletion mutant complementary RNA (synthesized in vitro using purified deletion mutant DNA and *Escherichia coli* RNA polymerase). Fingerprint analysis of the proteins produced showed that they contained most, if not all, of the methionine peptides common to small t and large T. Furthermore, the fragments of small t produced in response to dl 884 and dl 890 lacked two methionine peptides that were present in small t but not in large T. The results provide direct evidence that the region between 0.59-0.54 map units on SV40 DNA codes for polypeptide sequences that are unique to small t, and they establish that the nucleotide sequences from this region are both a coding sequence (for small t) and an intervening sequence (for large T). (38 refs)

78-6921 Selective Degradation of Newly Synthesized Nonmessenger Simian Virus 40 Transcripts.

(Eng) Chiu, N. H. (Lab. Biology Viruses, Natl. Inst. Allergy and Infectious Diseases, NIH, Bethesda, MD, 20014); Radonovich, M. F.; Thoren, M. M.; Salzman, N. P. *J Virol* 18(2): 590-599; 1978.

Under pulse-chase conditions with glucosamine, the processing, transport, and degradation of a relatively homogeneous population of nuclear viral RNA molecules (nvRNA) labeled during a brief pulse were examined 45 hr postinfection. By pretreating the simian virus 40-infected BSC-1 cells with glucosamine, ³H-uridine labeling of cellular and viral RNA could be halted immediately by the addition of cold uridine. Both messenger and nonmessenger regions of the late strand were transcribed during the 5-min labeling period and, after various chase periods, nvRNA's that sedimented at 16S, 17.5S, and 19S were observed. The fraction of the late strand that did not give rise to stable late messenger RNA (50% of nvRNA) was degraded rapidly, with a half-life of 8 min. A 40% fraction was transported to the cytoplasm, and the remaining 10% was sedimented from the nucleus at 2S-4S. These 2S-4S nvRNA's had a half-life of 3 hr, and hybridization studies suggested that they were partly coded for by the late-strand nonmessenger region and were derived from the initial nuclear processing step. Another part was coded for by the late-strand messenger region and may result from cleavage of 19S RNA into 17.5 and 16 S RNA's. Transport of nvRNA into the cytoplasm was detected after a 5-min pulse and a 7-min chase. Accumulation in the cytoplasm was maximal after a 30-min to 1-hr chase. At least two viral cytoplasmic species were noted: 19S (half-life 2 hr), which is likely transported directly from the nucleus, and 16S (half-life 5 hr), which may be formed by cleavage of the larger species in the nucleus and/or cytoplasm. 78-6922 Does Simian Virus 40 DNA Integrate into Cellular DNA During Productive Infection? (Eng)

Rigby, P. W. (Dept. Biochemistry, Imperial Coll. Science and Technology, London SW7 2AZ, England); Berg, P. *J Virol* 28(2): 475-489; 1978.

The possibility that simian virus 40 (SV40) DNA becomes covalently integrated into the chromosomal DNA of productively infected cells was investigated by isolating and purifying SV40 DNA late after infection of African green monkey kidney cells. This fraction contained large amounts of SV40 DNA sequences, but their behavior in electron microscope and restriction endonuclease mapping experiments indicated that most, if not all, of the viral DNA was not covalently joined to cellular DNA. Instead, it was organized into large, tandem, head-to-tail polymeric structures of wholly viral origin. The results showed that heteroduplexes between high-mol-wt SV40 DNA and a mutant SV40 DNA probe were not formed unless the former was digested with *EcoRI* or *HpaII*, enzymes that cleave SV40 DNA once. The electrophoretic mobility of the high-mol-wt SV40 DNA was not

perceptibly altered by digestion with several restriction endonucleases that cleave cellular DNA but not SV40 DNA. However, digestion with *EcoRI*, *HpaII*, *KpnI*, or *TaqI* converted all the SV40 DNA into unit-length, linear molecules. The high-mol-wt SV40 DNA was highly infectious in the standard plaque assay, and this infectivity was increased by digestion with *EcoRI* or *HpaII*. Because the polymers appeared upon extensive replication of the viral DNA and homopolymers were produced after coinfections with two physically distinguishable SV40 genomes, it is concluded that they are synthesized by a replicational mechanism. Although the data cannot exclude a low level of SV40 DNA integration during productive infection, sedimentation criteria used previously to demonstrate integration are misleading because novel forms of viral DNA, which copurify with cellular DNA, mimic integrated genomes. (46 refs)

78-6923 Presence of Histone H1 in the Chromosome of SV40 Virions Isolated from the Nuclei of Infected Cells. (Rus) Nedospasov, S. A. (Inst. Molecular Biology, Moscow, USSR); Bakaev, V. V.; Georgiev, G. P. *Dokl Akad Nauk SSSR* 241(2): 485-487; 1978.

The isolation of virions of simian virus 40 (SV40) from infected CV-1 monkey cells is described. Cells were incubated with ³H-thymidine (2 µCi/ml) and ¹⁴C-amino acids (5 µCi/ml) for 72 hr, washed, and centrifuged; the supernatant was then centrifuged in a sucrose gradient. The DNA radioactivity curve contained two distinct peaks, one 60S and the other at 200S. The peaks of protein radioactivity coincided with the peaks of DNA radioactivity. Electron microscope analysis of material from each peak showed that the light peak contained particles with a diameter (approx 250 Å) that corresponded to that of the native compact form of free SV40 minichromosomes. The heavy peak contained typical mature SV40 virions (420-450 Å in diameter) with clearly visible capsomers. Sodium dodecyl sulfate-polyacrylamide gel electrophoresis detected all five histones (including histone H1) in both the free minichromosomes and the virion particles. The ratio of histone H1 to the other histones was stoichiometric (1 molecule of H1/nucleosome). These findings indicate that the mature virus particle contains a chromosome that is extremely similar to the chromosome of the eukaryotes. (13 refs)

78-6924 Expression of Simian Virus 40 Early Genes in Transformed Rat Cells is Correlated with Maintenance of the Transformed Phenotype. (Eng) Gaudray, P. (Centre de Biochimie, Université de Nice, Parc Valrose, 06034 Nice, France); Rassoulzadegan, M.; Cuzin, F. *Proc Natl Acad Sci USA* 75(10): 4987-4991; 1978.

Experiments that show a clear temperature-dependence of the synthesis of all the immunoprecipitable tumor (T) antigenic polypeptides in the temperature-sensitive *A-N* (*tsA-N*)

simian virus 40 (SV40) transformants, but not in *tsA-A* SV40 transformants, are presented. Early viral polypeptides synthesized in SV-transformed FR 3T3 rat fibroblasts were identified by immunoprecipitation using anti-T antigen immune serum. Four polypeptide classes were identified, none of which was detectable in extracts of nontransformed cells or precipitated from transformed cell extracts by nonimmune serum. Their apparent mol wts were 92,000, 63,000, 56,000, and 19,000 daltons. A similar pattern was observed in extracts from lytically infected cells, but there was a reproducible quantitative difference between the relative amounts of immunoprecipitable polypeptide species in lytic and transformed cell extracts: the middle T 56,000- and 63,000-dalton species amounted to 5%-8% of the total T antigen-associated radioactivity in lytic cell extracts, compared with 20%-30% in transformed cells. It appears unlikely that these components result from random proteolysis or any other chemical modification in extracts. Previously reported evidence suggests that these middle T polypeptides may represent virus-coded polypeptides, produced by translation of independent spliced messenger RNA's or by post-translational processing of a larger viral polypeptide (large T); alternatively, they may be cellular gene products in a specific and stoichiometric association with viral proteins. In ³⁵S-methionine-labeled *tsA30-A* transformants, which maintain the transformed phenotype at high temperature, only minor quantitative variations in the pattern of T antigen synthesis were observed when the cultures were shifted from 33 C to 40.5 C. In contrast, the labeling rate of the four virus-specific polypeptides decreased by 90% or more at the high temperature in the *tsA-N* transformants. In all cases, a coordinated variation of the radioactivity associated with the different polypeptide classes was observed. These results suggest that the synthesis and/or processing of early viral proteins is controlled by different mechanisms in various types of SV40 transformants, and that it may be under the positive control a virus-coded protein in transformed N cells. 78-6925 Neoplastic Transformation of Permissive Monkey Cells by Subgenomic Fragments of SV40 DNA and Rescue of SV40 Virions from Transformed Cells by Cell Fusion. (Eng) Moyer, R. C. (Thorman Cancer Res. Lab., Trinity Univ., San Antonio, TX, 78284); Moyer, M. P.; Gerodetti, M. H. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2 Part 1), 2404 pp.; 1443-1464; 1978.

The *EcoRI*/*Hap A* fragment of simian virus 40 (SV40) DNA, which comprises 74% of the viral genome including the early region, and the *EcoRI*/*Hap B* fragment, which comprises 26% of the genome including most of the late regions, were tested for their ability to transform permissive TC7/CV-1 monkey cells. The two fragments were separated by electro-

phoresis and added to cell cultures in the presence of diethylaminoethyl-dextran. Results of indirect immunofluorescence tests revealed that either fragment transformed the cell without evidence of cytopathology or V antigen. Cells transformed by the 74% fragment displayed SV40 T antigen and were tumorigenic in newborn hamsters, but cells transformed by the 26% fragment appeared to express a new antigen and were not tumorigenic. Fusion of cells transformed by both types of fragments resulted in SV40 cytopathology and antigen production, which indicated that the two defective provirus complements were rescued to produce infectious virions. An "alien DNA" hypothesis is proposed to account for virus-induced and other forms of neoplasia. (61 refs)

78-6926 Growth Control in Simian Virus 40-transformed Rat Cells: Temperature-independent Expression of the Transformed Phenotype in *tsA* Transformants Derived by Agar Selection. (Eng) Rassoulzadegan, M. (Centre de Biochimie, Universite de Nice, Parc Valrose, 06034 Nice, France); Perbal, B.; Cuzin, F. *J Virol* 28(1): 1-5; 1978.

Fischer rat fibroblasts (FR 3T3) were infected with a temperature-sensitive simian virus 40 (SV40) mutant (*tsA30*) using transformed lines isolated from foci (*tsA30-N*) or from colonies grown in soft agar (*tsA30-A*). All (4/4) of the *tsA-A* transformants expressed the transformed phenotype at 40.5 C, but 2/3 *tsA-N* lines were temperature dependent for all the transformation characteristics studied. The pattern of temperature-dependent vs temperature-independent maintenance in these transformants thus appears similar to that found previously for transformed lines isolated after infection with polyoma virus *tsA* mutants. Temperature-shift experiments fused to CV-1 monkey cells indicated that all the *tsA-A* transformants carry mutant endogenous viral genomes. SV40 tumor antigen could be detected by immunofluorescence in all of the transformants at 33 C. Two distinct patterns of immunofluorescent staining were seen: all transformants of *tsA-A* showed homogeneous nuclear staining, but all the *tsA-N* showed a heterogeneous pattern. These results suggest that distinct modes of regulation of tumor antigen synthesis might be associated with the A and N mechanisms of transformation. (18 refs)

78-6927 Mapping of Early SV40-Specific Functions by Microinjection of Different Early Viral DNA Fragments. (Eng) Mueller, C. (Institut für Molekularbiologie und Biochemie, Freien Universität Berlin, W. Berlin 33, Arnimallee 22, Germany); Graessmann, A.; Graessmann, M. *Cell* 15(2): 579-585; 1978.

The ability of simian virus 40 (SV40) DNA fragments containing 60%-100% of the early genome region to induce early virus-specific functions in monkey and mouse kidney cells was studied. The following early virus-specific events were

ected 24 hr after microinjection of SV40 DNA I or its in vitro transcript, cRNA complementary to the early viral DNA strand: intranuclear tumor (T) antigen and U antigen accumulation; stimulation of cellular DNA synthesis; initiation of late SV40 gene expression; and induction of adenovirus 2 fiber protein synthesis. Proteins with T antigenicity were efficiently synthesized in cells after microinjection of any of the four SV40 DNA fragments sharing a common end of about 0.73 map unit and containing 58%-100% of the early genome. Cells injected with fragment Bgl I/Bam HI-A, which contains 100% of the early genome, were T-antigen-negative. Only the full-length early fragment Hpa II/Bam HI-A induced the remaining early SV40-specific functions. The data indicate that only an intact early viral protein can stimulate both viral and cellular DNA synthesis, DNA sequences at map position 0.67 being required for intracellular early viral transcription. (41 refs)

78-6928 Transforming Viruses Directly Reduce the Cellular Growth Requirement for a Platelet-Derived Growth Factor. (Eng) Scher, C. D. (Dept. Pediatrics, Sidney Farber Cancer Inst., Boston, MA, 02115); Pledger, W. J.; Martin, P.; Antoniades, H.; Stiles, C. D. *J Cell Physiol* 137(3, part 1): 371-380; 1978.

The ability of early passage mouse embryo fibroblasts, mouse 3T3 cells, early passage diploid human fibroblasts, and 3T3 cells and human fibroblasts transformed by simian virus 40 (SV40) or retroviruses to grow in medium supplemented with defibrinogenated platelet-poor plasma (PPP) was studied. The untransformed cells grew to higher cell densities in medium supplemented with serum than in medium supplemented with PPP. However, the human fibroblasts displayed this differential growth response only in the presence of hypophysiologic concentrations of calcium. When heated (100 C) extracts of human platelets were added to PPP-supplemented medium, growth of human and mouse embryo fibroblasts was the same as that in serum-supplemented medium. Fibroblasts transformed with SV40 or retroviruses grew to the same densities in medium supplemented with serum of PPP. Infection of BALB/c-3T3 cells with SV40 rapidly induced them to grow in PPP medium, whereas 3T3 cells infected but not transformed by retroviruses did not replicate in PPP medium. Cells that did not proliferate well in PPP medium did not form tumors when inoculated into athymic nude mice, whereas many of the lines that grew well in PPP medium were tumorigenic in nude mice.

78-6929 Another Chromosomal Assignment for a Simian Virus 40 Integration Site in Human Cells. (Eng) Kucherlapati, R. (Dept. Biochemical Sciences, Princeton Univ., Princeton, NJ, 08540); Hwang, S. P.; Shimizu, N.; McDougall, J. K.; Botchan, M. R. *Proc Natl Acad Sci USA* 75(9): 4460-4464; 1978.

Hybrid cell lines between B82, a murine cell line deficient in thymidine kinase (TK), and GM637, a simian virus 40 (SV40)-transformed human fibroblast cell line, were analyzed for SV40 T antigen (T-ag), V antigen (V-ag), and integrated viral DNA. Total high-mol wt DNA from GM637 was separated from free viral DNA by sucrose gradient fractionation and agarose gel electrophoresis. This high-mol-wt DNA was hydrolyzed with restriction endonuclease *BalI*, and SV40 DNA was detected by blot hybridization. Only one band containing SV40 DNA was consistently noted in GM637 and eight other hybrid cell DNA preparations, all of which were T-ag-positive. Cells lacking this viral DNA band were all T-ag-negative. Indirect immunofluorescence studies failed to show a correlation between the presence of T-ag and the human TK gene, which is located on chromosome 17, indicating that SV40 was not integrated on human chromosome 17. Likewise, none of the 16 gene markers tested, representing 14 different chromosomes, correlated with the presence of T-ag. Chromosome analyses of 20 B82/GM637 hybrid cell lines showed that, with one exception, the only chromosome present in all T-ag+ cell hybrids was chromosome 8. All hybrids that were T-ag+ had a single band of DNA that hybridized with SV40 DNA and migrated to the same position in all hybrids, indicating that the position of the viral sequences in the hybrids was stable. These data and those of earlier studies indicate that SV40 can integrate at one of several sites in the human genome and that this process is not chromosome specific. (30 refs)

78-6930 Viable Deletion Mutants in the Simian Virus 40 Early Region. (Eng) Feunteun, J. (Institut de Recherches Scientifiques sur le Cancer, B.P. no. 8, 94800-Villejuif, France); Kress, M.; Gardes, M.; Monier, R. *Proc Natl Acad Sci USA* 75(9): 4455-4459; 1978.

Simian virus 40 (SV40) mutants that have lost the unique site for the restriction enzyme *Taq* I at 0.565 were developed in monkey CV-1 cells in order to isolate *hr-t*-like SV40 mutants. Purified *taq* I linear SV40 DNA (50 µg/ml) was exposed to λ 5'-exonuclease (20 µg/ml) at 0 C for 30 min in 67 mM glycinate buffer, pH 9.4/2.5 mM MgCl₂, and then used for plaque assay on CV-1 cells. Five *Taq* I-resistant clones were purified, and DNA from each was prepared for restriction enzyme analysis using *Hind*III, *Hinf*I, *Alu* I, and *Hae* III. Two deletion classes were seen, both located at 0.565 on the genome. One deletion was approx 20-30 base pairs long, the other approx 250-310 base pairs long. To characterize the T antigens present in these deletion mutants, CV-1 cells infected with the mutants were labeled for 3 hr with ³⁵S-methionine and subjected to immunoprecipitation followed by gel electrophoresis. No difference was noted between any of the mutants and wild-type large T antigen. Wild-type small t antigen (t-ag), however, was missing from the mutants; in four mutants it was replaced by new polypeptides of mol wt 18,500, 17,000, 16,500, and 12,500 in greatly reduced quantities. In the fifth mutant, no t-ag of any type was detectable. The low yield of t-ag antigen was not due to a rapid turnover, and in

mixed infections the respective yields of wild-type and mutant t-ag were as expected. Thus, the deletions affect a region that is part of the t-ag coding sequences, but not those of large T antigen. Like *hr-t* polyoma mutants, the transforming ability of these cells, as measured by growth induction in agar, was clearly altered. A second complementation group in the SV40 early region is therefore defined by virtue of the fact that these mutants can complement a *tsA* mutant for transformation. (27 refs)

78-6931 Are the SV40 Induced Antigens and the Morphology of SV40 Transformed Cells Correlated (Meeting Abstract)? (Eng) Weller, N. K. (Dept. Molecular, Cellular and Developmental Biology, Univ. Colorado, Boulder, CO). *J Cell Biol* 79(2, part 2): 405a; 1978. (no refs)

78-6932 Regulation of SV40 T Antigen in SV40 Transformed Mouse Cells (Meeting Abstract). (Eng) Axelrod, H. R. (Dept. Biochemistry, Princeton Univ., Princeton, NJ); Levine, A. J. *J Cell Biol* 79(2, part 2): 401a; 1978. (2 refs)

78-6933 Induction of Infectious Virus DNA and Virus Particles by Mitomycin C in SV40-Transformed Mouse Cells. (Eng) Lavialle, C. (Institut de Recherches Scientifiques sur le Cancer, B.P. No. 8, 94800-Villejuif, France); Suarez, H. G.; Morris, A. G.; Cassingena, R. *J Gen Virol* 41(1): 201-205; 1978.

The efficiency of mitomycin C (MC) in inducing simian virus 40 (SV40) in nonpermissive mouse cells was investigated. Following infection of 3T3-4E Swiss mouse cells with SV40 (multiplicity of infection, 100 plaque-forming units/cell), an SV40-transformed cell line (SV/3T3-4E) was isolated and four independent clones were derived. The parental line and three of the clones (1, 2, and 4) spontaneously produced small amounts of infectious virus DNA but treatment of these cells with MC (0.3-3.0 $\mu\text{g}/\text{ml}$) enhanced the yield of virus DNA 10- to 100-fold. Infectious virus particles, never detected in untreated cultures, were occasionally induced by MC in the parental line and in clones 1, 2 and 4. A correlation was found between the level of SV40 DNA inducibility of a given clone and its capacity to produce virions in detectable amounts after MC treatment. It is concluded that SV/3T3-4E cells contain small amounts of free infectious SV40 DNA and that most cells in the parental line are capable of producing SV40 DNA spontaneously. (16 refs)

78-6934 Genetics of SV40 T-Antigen Expression: Studies of Twins, Heritable Syndromes and Cancer Families. (Eng) Blattner, W. A. (Environmental Branch,

NCI, Bethesda, MD, 20014); Lubiniecki, A. S.; Mulvihill, J. J.; Lalley, P.; Fraumeni, J. F. *Int J Cancer* 22(3): 231-238 1978.

The susceptibility of human skin fibroblasts to simian virus 40 (SV40) infection has been suggested as a marker of high risk for leukemia and, possibly, other cancers. To search for a pattern of genetic transmission, fibroblasts from 9 pairs of identical twins (in 7 pairs, one co-twin had acute leukemia in 1, both had aplastic anemia) and from 129 members of 21 cancer-prone families (including 16 members with cancer) were tested for SV40 tumor (T) antigen expression (SVTAE) in a 3-day immunofluorescence assay. The variance of T-antigen values was significantly less in identical than in fraternal twins or nontwin sibs (taken from cancer-prone or control families), suggesting a heritable component in the regulation of SV40 infection. In the families, SV40 T-antigen values of parents and children, as determined in the fibroblast immunofluorescence assay, were compared to models of Mendelian inheritance. At least three modes of inheritance, autosomal dominant, recessive, and x-linked, were observed. There was a tendency for offspring values to be distributed unimodally with respect to parental values. With the exception of Fanconi's anemia, the values for patients with cancer or predisposing syndromes were not elevated uniformly. The findings suggest that the genetic regulation of T-antigen expression is complex and, since no one pattern clearly predominates, probably accounts for a lack of disease effect of SVTAE. Thus, the utility of SVTAE as a marker of cancer risk appears limited. (35 refs)

78-6935 Quantitative Correlation Between Simian Virus 40 T-Antigen Synthesis and Late Viral Gene Expression in Permissive and Nonpermissive Cells. (Eng) Graessmann, A. (Institut fuer Molekularbiologie und Biochemie, Freien Universitaet Berlin, W. Berlin 33, W. Germany); Graessmann, M.; Guhl, E.; Mueller, C. *J Cell Biol* 77(1): R1-R8; 1978.

The intranuclear synthesis and accumulation of simian virus 40 (SV40) tumor (T) antigen was investigated by immunofluorescence and cytofluorometry in permissive CV1 monkey cells and nonpermissive 3T3 mouse cells at different times after infection. CV1 cells accumulated T antigen continuously over a 48-hr period after infection, whereas in 3T3 cells the T-antigen content remained constant and at a comparatively low level. Only those CV1 cells that had attained a threshold concentration of intranuclear T antigen [28 arbitrary units (AU)] synthesized viral capsid proteins (V antigen). Nearly 100% of nonpermissive 3T3 cells infected with 500 plaque-forming units of SV40 became T-antigen positive at 65 hr postinfection, but V antigen was not detected at any time. The minimum T-antigen threshold value (52 AU) for V-antigen synthesis in the nonpermissive cells was attained by microinjecting the cells with large amounts of SV40 DNA. The 3T3 cells may synthesize T antigen less efficiently and/or degrade it at a higher rate than monkey cells. Since the in-

nuclear presence of at least 250-500 viral particles or viral NA molecules overcomes nonpermissiveness, an early event in the infectious cycle (adsorption, penetration, intracellular release) must be involved in the nonpermissive type of response in infected mouse cells. (23 refs)

78-6936 Studies of Simian Sarcoma and Simian Sarcoma-associated Virus. II. Isolation of the Major Viral Glycoprotein, Properties of This Component and Specific Antiserum. (Eng) Thiel, H. J. (Dept. Surgery, Duke Univ. Medical Center, Durham, NC, 27710); Beug, H.; Graf, T.; Schwarz, H.; Schafer, W.; Bergholz, C.; Deinhardt, V. *Virology* 90(2): 360-365; 1978.

The characteristics of the major virus glycoprotein (gp) of the simian sarcoma virus complex (SSV) were studied. The glycoprotein, designated gp70, was isolated in highly pure form from virus-free supernatants of tissue culture medium using immunoadsorbents. SSV gp70 easily degraded to a 100,000-dalton product designated gp45. Both gp preparations appeared to be serologically and immunologically homogeneous. Antiserum prepared in rabbits to the purified SSV gp70 had a high neutralizing titer against SSV and was strongly cytotoxic for SSV-producing cells. The serum seemed to react mainly in a type-specific fashion with minor amounts of group and no interspecies reactivities. The interspecies reactivity of gp45 was somewhat reduced in comparison with gp70. (14 refs)

78-6937 Activation of Endogenous Type C Virus in BALB/c Mouse Cells by Herpesvirus DNA (Oncornavirus Activation/Transfection). (Eng) Boyd, A. L. (Viral Oncology Program, Frederick Cancer Res. Center, Frederick, MD, 21501); Derge, J. G.; Hamper, B. *Proc Natl Acad Sci USA* 75(9): 4558-4562; 1978.

Several virion and nonvirion DNA's were tested for their ability to activate endogenous C-type virus in BALB/c-derived mouse cells using the calcium precipitation technique. The DNA's from all herpesviruses (HV's) tested activated xenotropic C-type virus synthesis, whereas under the same conditions the DNA's from vaccinia virus and simian virus 40 were negative. Activation of C-type virus by HV DNA's was essentially linear up to about 0.2 µg DNA, but a decrease was usually observed at DNA concentrations ≥1 µg. Activation was also observed with UV-irradiated HV's, but not with irradiated vaccinia virus. Activation of C-type virus by DNA from herpes simplex virus (HSV) was observed after shearing or sonication of the DNA to an av size of 10⁶ daltons, but it was not observed with DNA sonicated to an av size of 1 x 10⁶ daltons. Alkali denaturation of DNA from HSV or treatment of the DNA with DNase, but not with DNase, destroyed its ability to activate C-type virus, as did crosslinking of the DNA with 4,5',8-trimethylpsoralen and light. The results suggest that HSV may function as a cocarcinogen. (20 refs)

78-6938 Physical Mapping of Herpes Simplex Virus-induced Polypeptides. (Eng) Marsden, H. S. (MRC Virology Unit, Inst. Virology, Univ. Glasgow, Glasgow G11 5JR, Scotland); Stow, N. D.; Preston, V. G.; Timbury, M.C.; Wilkie, N. M. *J Virol* 28(2): 624-642; 1978.

Correlation of the types of polypeptides induced by 29 herpes simplex virus type 1/type 2 intertypic recombinants with the crossover points in the recombinant DNAs enabled the map positions of many polypeptides to be deduced. The location on the physical map of 25 ³⁵S-methionine-labeled polypeptides, 11 phosphorylated polypeptides, and 4 glycosylated polypeptides was identified. Together with data from a previous study on the mapping of five immediate-early polypeptides, the results show that representatives of four groups of protein-immediate-early, late, phosphorylated, and glycosylated-map in both long and short regions. The functional organization of the herpes simplex virus genome does not therefore restrict any of these four groups to either the long or the short region. (19 refs)

78-6939 Antibodies to Herpes Simplex Virus in Cervical Cancer. (Jpn) Ishiguro, T. (Dept. Obstetrics and Gynecology, Kansai Medical Univ., Moriguchi-shi, Osaka Prefecture 570, Japan); Ozaki, Y. *Adv Obstet Gynecol (Jpn)* 30(1): 9-13; 1978.

Levels of antibodies to herpes simplex virus types 1 and 2 (HSV-1 and HSV-2) were measured in 79 Japanese patients with cervical cancer, 11 with dysplasia, and 155 controls (including 145 healthy women and 10 with ovarian cancer). There was no significant difference in mean antibody titers among these groups. Furthermore, 18.2% of the dysplasia patients, 16.7% of those with carcinoma in situ (CIS), 11.1% of those with early invasive cancer (EIC), 3.2% of those with invasive cancer (IC), 0% of those with advanced cancer (AC), and 8.3% of healthy controls had no antibodies to either virus. Statistically, these data were not significant (SNS). The prevalence of single infection with HSV-1, as defined by an HSV-2/HSV-1 ratio of ≤65, was 36.4% in dysplasia, 50.0% in CIS, 27.8% in EIC, 19.4% in IC, 27.8% in AC, and 31.7% in healthy controls (data SNS). The prevalence of HSV-2-positive women, as defined by an HSV-2/HSV-1 ratio of ≥93, was 9.1% in dysplasia, 0% in CIS, 16.7% in EIC, 11.1% in AC, and 9.0% in healthy controls (data SNS); however, the prevalence in IC was 19.4%, a rate significantly higher than that in healthy controls (p < 0.05). These results suggest that HSV-1 is not associated with cervical cancer or dysplasia and that HSV-2 is involved with the progression but probably not the initiation of cervical cancer. (13 refs)

78-6940 Preliminary Studies of a Non-Virionic Antigen Associated with Herpes Simplex Virus 1 and 2 (HSV₁-HSV₂). (Eng) Accinni, R. (Clinica Medica II dell'Universita di Milano, Milano, Italy); Ferrara, R.;

Tarro, G.; Sisillo, E.; Privitera, L.; Biancardi, C.; Bartorelli, A. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 199-210; 1977.

Nonvirion antigens of herpes virus (HSV₁) were studied radioimmunologically, by gel filtration on Sephadex G-200, and by polyacrylamide gel electrophoresis (PAGE). In the radioimmunological study, soluble extracts of normal or infected cells incubated with pathological sera were found to possess different immunological properties. Gel filtration demonstrated two peaks in pellet extracts from infected cells that were absent in analogous extracts from normal cell pellets. PAGE demonstrated that soluble extracts from suspensions of infected cells contained three radioactive bands that were absent in extracts from normal cells. (7 refs)

78-6941 Ultraviolet Reactivation of Herpes Simplex Virus Is Mutagenic and Inducible in Mammalian Cells. (Eng) Bandyopadhyay DasGupta, U. (Dept. Therapeutic Radiology, Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT, 06510); Summers, W. C. *Proc Natl Acad Sci USA* 75(5): 2378-2381; 1978.

Experiments were performed using the thymidine kinase (TK) locus of herpes simplex virus type 1 (HSV-1), strain Cl 101, to determine whether UV reactivation (Weigle reactivation) in mammalian cells is error-prone, thus leading to increased mutagenesis. The survival of UV-irradiated HSV-1 on UV-irradiated Vero cells was higher than that on unirradiated cells. A time lapse of 17 hr between irradiation of the host cells and infection with virus was needed to achieve max reactivation. In parallel experiments in which the frequencies of occurrence of the forward mutation in the TK gene of the virus were measured, growth of HSV-1 on UV-irradiated cells yielded progeny virus that had higher frequencies of TK- mutants than did progeny from infections of control cells. The time course of development of this mutagenic effect was the same as that for the development of UV-reactivation capacity. Furthermore, development of UV reactivation could be blocked by inhibition of protein synthesis. These findings suggest that an error-prone inducible UV-reactivation phenomenon exists in mammalian cells. (19 refs)

78-6942 Studies on the Synthesis and Structure of Herpes Simplex Virus RNA. (Eng) Stringer, J. R. (Univ. California, Irvine, Irvine, CA). *Diss Abstr Int [B]* 39(2): 511; 1978. (no refs)

78-6943 Temperature-sensitive Mutants of Herpes Simplex Virus Type 1. Defective in Transcription and Post-transcriptional Functions Required for Viral DNA Studies. (Eng) Parris, D. S. (Dept. Microbiology, Univ. Tennessee, Knoxville, TN, 37196); Courtney, R. J.; Schaffner, P. A. *Virology* 90(2): 177-186; 1978.

DNA- temperature-sensitive (*ts*) mutants of herpes simplex virus (HSV) representing four complementation groups (A, B, C, and D) were examined in temperature shift-down experiments to determine whether viral DNA synthesis is inhibited at the level of transcription or translation at the nonpermissive temperature. Synthesis of viral DNA after temperature shift-down appeared to require *de novo* transcription in the case of the *ts*A mutants, *ts*B2, and *ts*C4, but not in the case of *ts*D9. For *ts*B2 and *ts*C4, approx 2 hr was required for recovery of DNA synthesis capabilities following shift-down. Viral transcripts specifying proteins required for DNA synthesis were synthesized 2 hr postinfection in *ts*D9-infected cells at the nonpermissive temperature. Polypeptide synthesis by all four mutants following shift-down in the presence of an inhibitor was similar to that observed in mutant-infected cells maintained at the nonpermissive temperature in the absence of an inhibitor. Restoration of the wild-type pattern of viral polypeptide synthesis following shift-down in the presence of an inhibitor was greater for the groups A, C, and D mutants than from the group B mutants. 78-6944 Transformation of Hamster Embryo Fibroblasts by a Specific Fragment of the Herpes Simplex Virus Genome. (Eng) Camacho, A. (Dept. Microbiology, Univ. Chicago, Chicago, IL, 60637); Spear, P. G. *Cell* 15(3): 993-1002; 1978.

Isolated restriction endonuclease fragments of the herpes simplex virus type 1 (HSV-1) genome were introduced into hamster embryo cells to identify DNA sequences capable of transforming the cells with respect to acquisition of properties correlated with tumorigenicity. One of the fragments generated by cleavage of HSV-1 DNA with the restriction endonuclease *Xba*I induced transformation at a frequency of about 10 colonies per quantity of fragment recovered from 1 µg of uncut DNA; fractions containing the other *Xba*I fragments failed to induce transformation reproducibly, although occasional colonies were detected. The fragment with transforming activity (*Xba*I-F) is 15.5 x 10⁶ daltons in mol wt and is located between 0.30 and 0.45 map units on the HSV-1 genome. The *Xba*I-F transformants were selected for their ability to replicate in low concentrations of serum; in addition, they were found to attain high saturation densities in the presence of 10% serum and to form colonies in semisolid medium. Moreover, the transformed cells produced at least one viral gene product (a membrane glycoprotein) encoded in the fragment used for transformation, indicating not only that viral DNA was incorporated in the cells but that viral genes were expressed. 6945 **Genital Herpesvirus in the Etiology of Human Cervix Uteri Cancer.** (Eng) Kessler, I. I. (Dept. Epidemiology, Johns Hopkins Univ., Baltimore, MD, 21205). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): 1977. 1(part 1): 1193 pp.; 211-229; 1977.

Investigations of the possible role of herpesviruses in cervical cancer (CC) were made. The first was a retrospective, case-control study of 350 Yugoslavian women with histologically confirmed squamous carcinoma of the uterine cervix and 350 matched controls. Herpes simplex virus type 2 (HSV-2) antibody titers were higher among the CC patients than the controls. The relative risk of CC in women positive for HSV-2 was significantly increased, even after adjustments were made for the effects of 34 epidemiologic factors associated with CC. In addition, compared with controls, women who developed CC were more likely to smoke and drink alcoholic beverages, they had higher blood pressures, their parents tended to be older at their birth, they had more multiple marriages and an earlier start of sexual activity, consistently reduced coital frequency, and they were more likely to have abnormal menstrual histories. There was an unexpected two- to threefold greater mortality, especially at younger ages, of the first husbands of the CC patients, compared with the control first husbands. In a second study, still in progress, large groups of women are being observed: one married men who, at some other time, had wives who developed CC and a second married to men without such histories. To date, abnormal pap tests have been found in 13.6% of the "case" wives vs 7.2% of the control wives. CC or carcinoma in situ has been diagnosed in 3.5% of the case wives and 1.2% of the control wives. These data support an etiological role for HSV-2 in CC and they suggest that hormonal factors may also be involved. (23 refs)

6946 **Evaluation of the Effects of Phosphonoacetic Acid and 2-Deoxy-D-glucose on Herpesvirus Saimiri and Epstein-Barr Virus.** (Eng) Ablashi, D. (CI-Frederick Cancer Res. Center, Fort Detrick, Frederick, MD, 21501); Armstrong, G.; Fellows, C.; Easton, J.; Carson, G.; Twardzik, D. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 245-261; 1977.

The effect of phosphonoacetic acid (PAA) and 2-deoxy-D-glucose on *Herpesvirus saimiri* (HVS) and on Epstein-Barr virus (EBV) was studied in vitro. PAA significantly and reversibly inhibited the replication of HVS in African green monkey kidney (Vero) cells when it was added immedi-

ately after a 2-hr absorption period, but not later. The compound had no effect on the virus itself, on viral absorption, or on the induction of early antigen, but it did inhibit the production of late and membrane antigens almost completely. The failure of more template to reverse the inhibition of Vero cell DNA polymerases by PAA suggests that PAA does not interact with the uncoated DNA of input HVS in Vero cells. Rather, PAA may block a cellular process essential for HVS replication. PAA had no effect on the induction of endogenous or exogenous EBV early antigen, and it did not inhibit the appearance of EBV nuclear antigen in actively replicating Raji cells. Thus, the compound may have no effect on the replication of EBV DNA in Raji cells. This DNA is either integrated with the cell genome or in a free circular form. However, under certain conditions, PAA inhibited the expression of EBV membrane and viral capsid antigens. If the resistance of HVS to PAA, beginning 2 hr after the end of absorption, is similar to that of EBV DNA in Raji cells, infecting HVS DNA may assume a relatively stable and resistant form within the infected cell. It is not known if this would involve integration of input HVS DNA with the cellular genome. 2-Deoxy-D-glucose had no effect on HVS. (30 refs)

78-6947 **Host Cell Reactivation of Epstein-Barr Virus in Normal and Repair-defective Leukocytes.** (Eng) Henderson, E. E. (Dept. Microbiology and Immunology, Temple Univ. Sch. Medicine, Philadelphia, PA, 19140). *Cancer Res* 38(10): 3256-3263; 1978.

Epstein-Barr virus (EBV)-induced transformation efficiencies were quantitated for peripheral blood WBC from two patients with xeroderma pigmentosum (XP) and a patient with Cockayne's syndrome. No differences in transformation efficiencies were observed among XP, Cockayne's syndrome, or normal adult WBC, as judged by transformed centers or limiting dilution assays. However, when either the WBC or the infecting EBV was UV-irradiated prior to virus exposure, XP WBC showed a greater decrease in ability to undergo in vitro transformation. The doses of the transforming functions of the B95-8 strain of EBV lethal to 37% of the animals were 70, 725, and 750 ergs/mm² when measured in XP, XP heterozygotic, and normal adult WBC, respectively. Transforming activity of UV-irradiated EBV could be partially restored by illuminating infected XP WBC with visible light 36 hr after virus exposure. Illumination with visible light had little effect on transformation of neonatal or normal adult WBC by UV-irradiated EBV. Colony formation in soft agarose by the resulting lymphoblastoid cell lines established from primary XP or Cockayne's syndrome WBC showed increased sensitivity to UV irradiation when compared with lymphoblastoid cell lines established from heterozygotic or normal individuals. These results indicate that EBV is similar to other herpesviruses in being subject to host cell reactivation and that the EBV-induced transformation does not require or alter these functions. (39 refs.)

78-6948 Detection of Epstein-Barr Virus in Biopsied Malignant Lymphoma Cell and Its Continuous Culture. (Eng) Suzuki, T. (First Dept. Pathology, Niigata Univ. Sch. Medicine, 1-Bancho, Asahimachi-dori, Niigata 951, Japan); Oboshi, S.; Ishihara, N.; Emura, I.; Ohnishi, Y.; Sairenji, T.; Hinuma, Y. *Gann* 69(2): 213-221; 1978.

The detection of the Epstein-Barr (EB) virus genome in the tumor cells from a patient with non-Burkitt-type B-cell lymphoma and the establishment of tumor cell lines (Fujimaki-I and -II) from these cells are described. More than 80% of the tumor cells obtained from a pericardial effusion of the patient were positive for EB nuclear antigen (EBNA), and herpes-type virus particles were detected in the tumor cell nuclei. Tumor cells from a biopsy specimen of the original sc tumor grew continuously in vitro without any cell death (Fujimaki-I) and tumor cells from the pericardial effusion proliferated without a growth lag phase or cell death (Fujimaki-II). The cytological characteristics of the Fujimaki-II cells were similar to those of the tumor cells in vivo. Seventy percent of these cells were positive for EBNA and 4% were positive for EB virus capsid antigen. The modal chromosome number of the cells in the twenty-fourth generation was 46, and no marker chromosomes were found. IgG was monoclonally demonstrated in the culture medium. Fatal generalized toxoplasmosis resulted when the original tumor tissue was inoculated ip, sc, or under the renal capsule in athymic nude mice. Fujimaki-II cells heterotransplanted sc or ip into mice did not induce tumors, and the virus released by these cells did not transform cord blood lymphocytes. These data suggest that the Fujimaki cells did not produce detectable amounts of infectious virus. This may be the first case of non-Burkitt type lymphoma in which the EB virus genome was directly detected in the tumor cells. (22 refs)

78-6949 A Study on Epstein Barr Virus Receptor Activity in Cell Free Extracts of Human Lymphoblastoid Cells. (Eng) Ng, M. H. (Dept. Microbiology, Queen Mary Hosp. Compound, Univ. Hong Kong, Hong Kong, China); Lui, S. W.; Chan, K. H. *Arch Virol* 58(3): 221-233; 1978.

The detection of Epstein Barr virus (EBV) receptor activity in the surface extract of Raji cells and to a lesser extent in that of BJAB cells both are B lymphoblastoid cells susceptible to EBV infection) is reported, and results of a preliminary attempt to purify the Raji cell receptors are also presented. Receptor activity was not detected in extracts of P₃HR-1 cells and human diploid fibroblasts, neither of which are known to be susceptible to EBV infection. Receptor activity in the Raji cell extract was found to be associated with membranous structures, which may have rendered the activity resistant to treatment with trypsin and sonication. The receptor activity was abrogated if the extract was exposed to neutral detergent. Binding of receptor activity was observed when Raji cell extract was chromatographed on a column of immobilized EBV

components. Subsequent electrophoretic analysis showed however, that this procedure did not result in an appreciable purification of the receptor activity. Neutral detergent-treated extract was similarly chromatographed. The resulting eluates did not contain detectable receptor activity but were heterogeneous in protein content compared with the original extract. It is uncertain if these EBV binding proteins are involved in the receptor activity of the extract. (17 refs)

78-6950 Expression of Altered Ribonucleotide Reductase Activity Associated with the Replication of the Epstein-Barr Virus. (Eng) Henry, B. E. (Dept. Microbiology, Univ. Mississippi Medical Center, Jackson, MS 39216); Glaser, R.; Hewetson, J.; O'Callaghan, D. J. *Virology* 89(1): 262-271; 1978.

Extracts of control and 5-iododeoxyuridine (IUdR)-induced epithelial/Burkitt hybrid cells (D98/HR-1) and Raji cells were assayed for ribonucleotide reductase (RR) activity in the presence and absence of hydroxyurea (HU). The expression of the Epstein-Barr virus (EBV) genome in these cells can be regulated by induction with IUdR or superinfection with the virus. HU inhibited the enzyme activity of control D98/HR-1 and Raji cells by > 70% at both low (2×10^{-4} M) and high (5×10^{-4} M) concentrations. However the reductase activities of IUdR-induced D98/HR-1 cells, Raji cells superinfected with EBV, and IUdR-induced Raji cells were resistant to both levels of HU; enzyme activities of 85% to > 100% of control values were obtained in all cases. Under conditions that allowed only partial expression of the EBV genome (before removal of IUdR; early time after superinfection), significant levels (70%-85%) of HU-resistant RR activity were obtained in the presence of 2×10^{-4} M HU, but only 30%-45% of control reductase activity was observed at the higher concentration. Mixing experiments employing combinations of various D98/HR-1 control and induced cell extracts indicated that the HU-resistant reductase activity of induced D98/HR-1 cells was due to altered enzyme activity and not to nonenzymatic factors. Experiments in which HU was preincubated with control and induced cell extracts showed that the HU-resistant RR in extracts of induced D98/HR-1 cells was not due to inactivation of the inhibitor by an enzyme or factor present in these cells. These findings, together with similar findings for equine herpesvirus type 1 and herpes simplex virus types 1 and 2, suggest that alteration of RR activity may be a key event in herpesvirus replication. (22 refs.)

78-6951 Epidemiological Evidence for Causal Relationship Between Epstein-Barr Virus and Burkitt Lymphoma from Ugandan Prospective Study. (Eng) de The G. (International Agency Res. Cancer, WHO, 150 cours Albert Thomas, 69372 Lyon, France); Geser, A.; Day, N. E.; Tukei, P. M.; Williams, E. H.; Beri, D. P.; Smith, P. G.

A. G.; Bornkamm, G. W.; Feorino, P.; Henle, W. *Nature* 267(5673): 756-761; 1978.

From 1972-1977, a large, prospective, seroepidemiological study was undertaken in Uganda to evaluate evidence that Epstein-Barr virus (EBV) is a necessary factor for the development of Burkitt's lymphoma (BL). From 1972 to 1974, 147 samples were taken from 42,000 children up to age 8. Of these, 31 cases of BL had been diagnosed in the area, 14 of which were in children originally bled. (Only 3/31 patients were missed at original bleeding; the rest were from a region covered by the field team or were too old for inclusion.) In 14 children, the interval between initial serum collection and BL onset was 7-54 mo. Significantly higher titers of antibodies (ab's) to virus capsid antigen (VCA) were seen in BL sera than in matched controls. These titers were indicative of the high ab levels associated with BL and present long before clinical onset. There were no marked differences in pre- and post-BL ab titers to herpes simplex and cytomegalovirus, eliminating the possibility that this was due to a long-standing defect in cell-mediated immunity. Six of seven patients with detectable EBV DNA in tumor tissue had prediagnosis VCA ab titers high or higher than those in controls. Thus, the association of BL with pre-diagnosis VCA titers may be confined to cases characterized by EBV DNA in the tumor cells. There may be two types of BL with different etiologies, one associated with EBV and predominantly in tropical areas and one not associated with EBV and found in temperate areas. The results strongly support a causal association between EBV infection and BL. However, even in a region where infection with EBV is nearly universal, only 1 child in 1,000 develops BL; therefore, other factors are required. The potential oncogenicity of EBV is realized only in exceptional circumstances. (45 refs.)

52 A New Manifestation of Infection with Epstein-Barr Virus. (Eng) Smith, H. (Dept. Infectious Diseases and Immunological Medicine, Northwick Hospital, Harrow HA1 3UJ, England); Denman, A. M. *British Medical Journal* 2(6132): 248; 1978.

A 47-year-old woman with a specific T-lymphocyte defect suffered a prolonged bizarre illness produced by Epstein-Barr virus (EBV). The illness was intermediate in severity and outlasted the common self-limiting infectious mononucleosis and the more aggressive malignant condition associated with this virus. Antibodies to EB virus capsid antigen (detected by immunofluorescence) showed a progressive rise in titer. It is suggested that the patient suffered from a specific defect in cell-mediated immunity to EBV, shown morphologically in her failure to produce atypical mononuclear cells and functionally in her inability to mount a specific reaction against cells infected by this agent. The patient's history of recurrent varicella indicated that there was a constitutional inability to react to DNA containing herpesviruses. The patient responded to treatment with corticosteroids. (4 refs)

78-6953 Study of Epstein-Barr Virus-determined Nuclear Antigen (EBNA) by Chromatography on Fixed Cell Nuclei. (Eng) Hirsch, I. (Dept. Experimental Virology, Inst. Sera and Vaccines, 101 03 Prague, Czechoslovakia); Suchankova, A.; Zavadova, H.; Vonka, V. *International Journal of Cancer* 22(5): 535-541; 1978.

A low concentration of NaCl (50 mM) and pH 6.0 were found to be optimal conditions for the in vitro conversion of Epstein-Barr virus nuclear antigen (EBNA)-negative nuclei to EBNA-positive forms by the addition of complement-fixing (CF) antigen from the Raji human lymphoblastoid cell lines. The conversion was sensitive to treatment with DNase but not RNase, which suggests that EBV-CF antigen binds specifically to nuclear DNA. Identical conditions were optimal for both the elution of EBNA from in vitro-converted nuclei and the adsorption and elution of EBV-CF antigen in DNA-cellulose chromatography. This indicates that the DNA-binding properties of EBNA antigen can be studied in a microchromatographic system employing fixed nuclei. The advantages of this method are its simplicity, capacity for analyzing many samples per experiment, and requirements of very small amounts of material. Elution patterns for EBNA were significantly different when nuclei from different cell lines (Raji, Ramos, and P3HR-1) were converted to EBNA positivity. EBNA was eluted from converted nuclei of EBV genome-positive P3HR-1 cells at an almost 0.1 M higher concentration of NaCl than was necessary for a similar degree of elution from nuclei of EBV genome-negative Ramos cells. (22 refs)

78-6954 DNA of Epstein-Barr Virus. IV. Linkage Map of Restriction Enzyme Fragments of the B95-8 and W91 Strains of Epstein-Barr Virus. (Eng) Given, D. (Dept. Medicine, Univ. Chicago, Chicago, IL, 60637); Kieff, E. *Journal of Virology* 28(2): 524-542; 1978.

The arrangement of restriction enzyme sites *EcoRI*, *Hsu I*, and *Sal I* in the DNA of the B95-8 and W91 isolates of Epstein-Barr virus (EBV) was determined from the size of the single-enzyme-cleaved fragments and from blot hybridizations that identify which fragments cut from the DNA with one enzyme contain nucleotide sequences in common with fragments cut from the DNA with a second enzyme. The data indicate that there is a consistent and unique sequence arrangement of approx 95 to 100 x 10⁶ daltons of B95-8 strain EBV DNA. Both termini were variable in length, but the opposite ends of the molecule contained homologous sequences. The high degree of homology between the opposite ends of the molecule and the similarity in size of the "additional" 500-base pair segments suggest that there are identical repeating units at both ends of the DNA. The size of almost all *EcoRI*, *Hsu I*, and *Sal I* fragments of W91 DNA was identical to that of the B95-8 DNA fragments except that W91 DNA contained approx 7 x 10⁶ daltons of "extra" DNA in the *Hsu I*-*EcoRI*-C overlap region of B95-8 DNA. Furthermore, the restriction endonuclease fragments of the W91

and B95-8 DNA's, which are of similar mol wt, had homologous nucleotide sequences. Moreover, the W91 fragments contained only sequences from a single region of the B95-8 genome. Two lines of evidence indicate that the extra DNA in W91 *Eco*RI C and *Hsu*I D₁ and D₂ fragments is viral DNA and not cellular. (48 refs)

78-6955 Electron Microscopic Studies of Tumor Viruses. II. Entry and Uncoating of Epstein-Barr Virus. (Eng) Miyamoto, K. (Pathology Div., Natl. Cancer Center Res. Inst., Tsukiji 5-1-1, Chuo-ku, Tokyo 104, Japan); Sairenji, T.; Hinuma, Y. *Microbiol Immunol* 22(8): 463-474; 1978.

The entry of Epstein-Barr virus into human lymphoblastoid cells (Daudi) was studied ultrastructurally. Two types of virions were observed on the cell surface: the zone separating the capsid from the dense core in one case was electron-translucent, but this zone in the other case was more dense because of the presence of finely granular material. These virions were referred to as light and dense particles, respectively. Virus attached to the cell surface at time 0 consisted of 56% dense particles, 41% light particles, and 3% empty particles (ie, devoid of cores). In samples taken at time 0, no free virus was found in the cell cytoplasm, although a few (<1%) of the cells showed degenerative changes. When the cells were warmed to 37 C, two distinct types of interaction between the viral envelope and cell membrane ensued, these changes being observed most frequently in samples taken at 30-60 min. The first change was simultaneous dissolution of both the viral envelope and cell membrane at the point of attachment, presumably resulting in passage of viral capsids into the cytoplasm. The other change was dissolution only of the cell membrane at the site of attachment, resulting in penetration of the enveloped virus. Envelope dissolution appeared to occur subsequently in the cytoplasm, with release of capsids. Fusion of the viral envelope with the cell membrane was not observed. Enveloped viruses may differ in the mechanism by which they gain entry and in their ability to cause cell fusion at early stages of infection. (21 refs)

78-6956 Acute Lymphocytic Leukemia in the Course of a Primary Herpes Infection with Hepatitis and Bone Marrow Aplasia in a Two-Year-Old Child. (Fre) De Lumley, L. (Travail du Service de Pédiatrie I, Centre Hospitalier Universitaire Dupuytren, 87000 Limoges, France); Malinvaud, G.; Boulesteix, J.; Gaillard, S.; Colombeau, M. C. *Pédiatrie* 33(3): 291-298; 1978.

Acute lymphocytic leukemia (ALL) developed in a 2-yr-old boy admitted to the hospital with viral hepatitis. Prior to admission, the child was given sulfamethoxazole, trimethoprim, and pipebuzone for fever and stomatitis. Acute hepatitis was diagnosed on the basis of fever, icterus, pruritis, and hepatomegaly. Blood studies revealed anemia, leukopenia

(10% polynuclear neutrophils, 90% lymphocytes), and thrombocytopenia. Viral serology was negative; however, there was a high level of antiherpes antibodies. The patient was treated with cefalotine, (125 mg/kg/day), gentamycin (4 mg/kg/day), prednisone (2 mg/kg/day), and RBC and WB transfusions. The cefalotin was replaced by colistin (1 million units/day) when a dermatitis reaction occurred. The patient improved and was well enough to leave the hospital on the 31st day with regression of hepatic and inflammatory symptoms. Four months after the initial admission, he was readmitted with clinical symptoms of a tumor, including hepatosplenomegaly and widespread adenopathy. A bone marrow puncture revealed 82% small lymphoblasts. Despite treatment with combination chemotherapy for ALL, the child died 17 mo after the first admission. The question arises as to whether the herpesvirus infection was severe as a result of a preleukemic condition or whether the herpesvirus was responsible for the ALL. (26 refs)

78-6957 Establishment of a Human Hepatoma Cell Line Which Produces Hepatitis B Surface Antigen (HBsAg). (Eng) Alexander, J. (Virus Cancer Res. Unit., Polio-myelitis Res. Foundation, Johannesburg, South Africa); Bey, E.; Macnab, G. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 321-330; 1977.

Biochemical and immunological studies were made of a cell line established from a primary liver carcinoma of a 24-yr-old man. One aim of the studies was to examine the cells for the presence of virus particles and viral antigens. The cells, which had been in continuous culture for 30 mo, had a male human chromosome pattern. The modal chromosome number was 56.6, and markers were present. The enzymes conformed to the human pattern, and glucose-6-phosphate dehydrogenase type A isozyme was found. Electron microscope studies showed that the cells contained glycogen granules and that microvilli and smooth endoplasmic reticulum were common. There was no evidence of virus particles, and there were no signs of lesions commonly associated with hepatitis-infected liver cells. The cells produced hepatitis B surface antigen (HBsAg), which was detected predominantly in the culture supernatant. The antigen levels increased with time, and antigen was produced at approx 500 µg/day/10⁶ cells. HBsAg activity in the culture supernatant was associated with amorphous particles ranging from 16 to 24 nanometers in diameter. The particles had a buoyant density in CsCl of 1.18-1.2 g/cm³. (23 refs)

78-6958 Hepatocellular Carcinoma Associated with HBs Antigen: A Study of 25 Cases from Vietnam. (Fre) Doury, J. C. (Laboratoire d'anatomie pathologique, In-

de Medecine tropicale du service de sante des armees, du Pharo, 13998 Marseille-Armees, France); Roche, J. B. *Rev Epidemiol Sante Publique* 26(2): 161-170; 1978.

orcein staining and indirect immunofluorescence on thin sections, hepatitis B surface antigen was demonstrated in 64% of 25 hepatocellular carcinomas (including 1 bone metastasis) in Vietnamese patients. Literature findings suggesting a causal role for hepatitis B virus in primary liver cancer are discussed. (29 refs)

5959 **A Virus Similar to Human Hepatitis B Virus Associated with Hepatitis and Hepatoma in Woodchucks.** (Eng) Summers, J. (Inst. Cancer Res., Fox Chase Cancer Center, Philadelphia, PA, 19111); Smolec, J. Snyder, R. *Proc Natl Acad Sci USA* 75(9): 4533-4537; 1978.

ence indicates that human hepatitis B virus (HBV) belongs to a novel class of DNA viruses that may be causative agents of hepatitis in species other than humans. Approximately 10% of the serum samples from woodchucks at a research laboratory contained DNA polymerase (Pase)-containing particles in amounts comparable to those found in hepatitis B surface antigen (HBsAg)-positive sera. Three animals (CW307, CW326, and CW316) subsequently died and were necropsied further to determine the possible relationship between the particles and hepatic lesions. CW307 and CW326 had hepatocellular carcinomas and evidence of chronic active hepatitis, and their sera contained detectable levels of endogenous DNA Pase, but serum from CW316, with no apparent hepatic lesions, had no detectable DNA Pase-containing particles. Large numbers of spherical and tubular forms approximately 30-40 nm in diameter were found in the serum of CW307 and CW326. They strongly resembled HBsAg, but floated at a slightly lower density in CsCl gradients. A second population of particles banding at 1.215 g/cm³ contained a DNA polymerase (Pase) activity. The DNA was similar in size and structure to HBV DNA. In addition, each DNA molecule appeared to contain a substantial single-stranded region, as in HBV DNA. The action of the internal DNA Pase on the single-stranded region accounts for the endogenous DNA Pase activity observed in the serum of some woodchucks. In the CsCl gradient, fractions of the gradient that had endogenous DNA Pase activity contained double-layered particles, 55 nm in diameter, that resembled Dane particles, thought to be the complete virus of hepatitis B. It is likely that these double-layered particles contain the DNA and DNA Pase activity. The double-layered particles found in the diseased woodchucks were similar but not identical to those associated with hepatitis B. Preliminary experiments indicate that the exposed antigenic sites on the small particles do not cross-react with HBsAg. (48 refs)

5960 **An Electroncytochemical Study of 5'-Nucleotide Phosphodiesterase in Hepatoma, Cirrhosis**

and Hepatitis. (Eng) Tsou, K. C. (Harrison Dept. Surgical Res., Sch. Medicine, Univ. Pennsylvania, Philadelphia, PA, 19104); Lo, K. W.; Rhoads, J. E.; Mackie, J. A. *In: Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 331-342; 1977.

Polyacrylamide gel electrophoresis analyses have recently shown that there is an isozyme of 5'-nucleotide phosphodiesterase (5'-NPDase) in the sera of patients with hepatitis B and hepatoma and in some with cirrhosis. To determine the significance of this enzyme in linking the etiology of hepatoma with hepatitis B-related virus, hepatoma tissues from two patients were studied ultrastructurally and electron cytochemically. The sera of these two patients were positive for 5'-NPDase and negative for hepatitis B surface antigen (HBsAg). α -Fetoprotein levels were 10 and 400 nanograms/ml, respectively. Both tumor samples were positive for viruslike particles resembling Dane particles of hepatitis B serum. These particles were also seen in cirrhotic areas of the liver, but most were found enclosed in cytoplasmic vesicles. One interesting feature of the cytoplasmic organelles was an abundance of circular vesicular membranes that often surrounded the mitochondria. This feature was also seen in the cirrhotic areas of both patients. An electron cytochemical method demonstrated the presence of deposits of 5'-NPDase activity on particles obtained by precipitation of hepatitis B serum with anti-HBsAg. These data suggest that there may be a group of human hepatomas etiologically linked to hepatitis B-associated virus and that some cases of cirrhosis may be a reflection of the host-immune response to viral proliferation. A possible role for 5'-NPDase in hepatitis B infection is suggested. (48 refs)

78-6961 **Liver Cell Dysplasia and Hepatitis B Surface and Core Antigens in Cirrhosis and Hepatocellular Carcinoma of Autopsy Cases.** (Eng) Sakurai, M. (1st Dept. Pathology, Osaka Univ. Medical Sch., Osaka, Japan). *Acta Pathol Jpn* 28(5): 705-719; 1978.

The relationships between cirrhosis, hepatoma, liver cell dysplasia, serum and cellular levels of hepatitis B surface and core antigens (HBsAg and HBcAg), and serum levels of antibody to HBsAg (anti-HBs) were studied based on examination of tissues from 180 autopsy cases with cirrhosis and/or hepatoma. Dysplasia was not associated with hepatoma in the absence of cirrhosis and was significantly more common in cirrhotic livers with tumors than in cirrhotic livers without tumors. The association between cirrhosis and dysplasia did not vary with age or sex. There was a significant correlation between high HBsAg levels and cirrhosis plus dysplasia, and orcein-positive cells were found significantly more often in cirrhotic livers than in noncirrhotic livers. The morphological characteristics of the orcein-positive liver cells could not

be correlated with dysplasia or hepatoma. HBcAg levels did not correlate significantly with dysplasia or hepatoma, but they did correlate with active cirrhosis, marked liver cell degeneration and necrosis, and membranous diffuse-type HBsAg in liver cells. (21 refs)

78-6962 Detection of Adenovirus Integration Sites in Host Cell Chromosomes. (Eng) McDougall, J. K. (Cold Spring Harbor Lab., Cold Spring Harbor, NY, 11524); Dunn, A. R.; Gallimore, P. H. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 129-137; 1977.

The location and function of integrated adenovirus (Ad) DNA sequences in rodent and human cells were determined by several approaches. Somatic cell hybrids were derived by fusion of virus-transformed rat cells and mouse cells deficient in thymidine kinase. The hybrid lines were isolated by a double selective system. Chromosomes (Chr) in the hybrids bearing mouse centromeres were identified by in situ hybridization with mouse satellite complementary RNA as the probe. The only rat Chr positively identified in the hybrid lines were 1, 2, 11, 12, 17, and 19; however, none of these Chr was consistently present in every hybrid line. All hybrids were screened for virus messenger RNA (mRNA) by in situ hybridization using ¹²⁵I-labeled Ad DNA. None of the six rat Chr identified was consistently present in viral mRNA or T-antigen-positive lines, and none of the 15 rat isozymes tested, apart from thymidine kinase, was always present in hybrid cells expressing viral functions. Thus, cytogenetic analysis and rat isozyme segregation data indicated that many hybrids contained new Chr translocations not present in the parental lines and that none of the marker Chr in the transformed cells appeared in the hybrid lines. The situation with an Ad-transformed human cell line was similar, in that these cells were heterogeneous in Chr constitution, with an average count in the triploid range and with only a small amount of viral DNA/diploid quantity of human DNA. Thus, Ad DNA is integrated into only a few Chr of rat cells, but it was not possible to define a specific Chr associated with the expression of Ad T antigen. (26 refs)

78-6963 Synthesis of a Structural Adenovirus Polypeptide in the Absence of Viral DNA Replication. (Eng) Persson, H. (Dept. Microbiology, Biomedical Center, Box 581, S-751 23 Uppsala, Sweden); Pettersson, U.; Mathews, M. B. *Virology* 90(1): 67-79; 1978.

The kinetics and control of adenovirus type 2 (Ad2) polypeptide IX (ppIX) synthesis were studied in HeLa cells pulse-labeled with ³⁵S-methionine at different times beginning at 2 hr postinfection. Cell extracts were immunoprecipitated

with antisera against Ad2 early polypeptides or structural components, and the immunoprecipitates were analyzed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). Polypeptide IX, a structural protein, was first detectable 6 hr postinfection, 4 hr before ppII and III, and 6 hr before ppIV, the major structural components. When cells were treated with cytosine arabinoside for 1 hr after Ad2 infection, ppIX antiserum precipitated a 12,000-mol-wt peptide that specifically comigrated with ppIX on SDS-PAGE thus demonstrating the synthesis of ppIX in the absence of viral RNA replication. Cycloheximide which blocks protein synthesis as well as viral replication, did not inhibit ppIX synthesis or accumulation of its messenger RNA (mRNA), although the mRNA's of the other structural components remained undetectable. RNA from cycloheximide-treated, virus-infected cells also directed the synthesis of a 12,000-mol-wt polypeptide that comigrated with ppIX and was precipitated by antiserum against ppIX. Size fractionation of the RNA indicated that it sedimented at the same rate, 9S, as the late mRNA for ppIX. Because transcription of this polypeptide occurs at a different time and is under different regulation than the other late structural genes, ppIX may have functions in addition to its structural role in the virus particle. (48 refs)

78-6964 The Spliced Structures of Adenovirus 2 Fiber Message and the Other Late mRNAs. (Eng) Chow, L. T. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY, 11524); Broker, T. R. *Cell* 15(2): 497-510; 1978.

Several rightward-transcribed (R)-strand transcripts in the adenovirus 2 (Ad2) map interval between coordinates 27 and 50 were mapped. In common with eight previously reported Ad2 messenger RNA's (mRNA's), four RNA species were identified with the same tripartite leader sequence derived from coordinates 16.6, 19.6, and 26.6. This leader was joined to messages with 5' ends located at coordinates 29.1, 30.5, 33.9, and 42.8, respectively. The RNA transcripts extending from 29.1 to 39.0 covered most or all of the virus-associated RNA genes (29.0-30.1). The late RNA's could be grouped into several families of transcripts that differed substantially in the coordinate at which the leader sequences were attached to the main body of message. The number of RNA species transcribed from the Ad2 chromosome between coordinates 29 and 50 exceeded the number of identified Ad2 proteins. A subpopulation of the polysomal mRNA's for the fiber protein, the most distal gene (86.3-91.2) in the rightward transcription unit, had a fourth leader component "y" (78.6-79.1) in addition to the common tripartite leader sequences. Less frequent fiber RNA species had a fifth "x" (79.6-77.3) and/or sixth "z" (84.7-85.1) leader segment. mRNA transcribed at late times from the L strand between coordinates 15.0 and 11.0 had a single component leader located 200 bases from the main body of the gene (coordinates 16.1-15.7). This leader originated from a site close to the first leader component (16.5-16.6) of the R-strand messages. (38 refs)

6966 **A Supplementary Adenoviral Leader Sequence and its Role in Messenger Translation.** (Eng) ...nn, A. R. (Cold Spring Harbor Lab., P.O. Box 100, Cold Spring Harbor, NY, 11524); Mathews, M. B.; Chow, L. T.; ...brook, J. *Cell* 15(2): 511-526; 1978.

The population of adenovirus 2-simian virus 40 (Ad2-SV40) hybrid messenger RNA's (mRNA's) generated late in the infection of HeLa cells with the Ad2-SV40 hybrid Ad2+ND1 dp2 was studied biochemically and by electron microscope heteroduplex analysis. During the course of lytic infection with the hybrid, a viral mRNA was synthesized whose 5' end included the start of the Ad2 fiber gene and whose 3' end lay in SV40 sequences. Two forms of this mRNA existed in the cytoplasm of HeLa cells at late times of infection. Both forms contained the conventional tripartite leader present on "late" Ad2 mRNA's, but they differed in the presence or absence of a fourth leader sequence consisting of 180 nucleotides of Ad2 sequences located 2,000 nucleotides upstream from the gene. Both forms of the hybrid mRNA were isolated by fractionation of total poly(A)-containing Ad2+ND1 dp2 late cytoplasmic RNA in methylmercuric hydroxide-agarose gels. It was established that the presence or absence of the fourth leader sequence had little or no influence on the ability of the messenger to direct the synthesis of the 23,000- to 24,000-dalton protein(s) in a cell-free translation system derived from rabbit reticulocytes. (23 refs)

6967 **Activation of RNA Particles from Human Tumors by Human Adenovirus.** (Eng) Winters, W. (Univ. Texas Health Science Center, San Antonio, TX); ...ri, A.; Sykes, J. A.; O'Toole, C. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 279-292; 1977.

Cultures of various human tumor and normal cells were grown in standard medium and inoculated with 5-500 plaque-forming units/cell of stock adenovirus 5 (Ad5). Cells of 15/20 sarcomas of different histologic types, 9/10 melanomas, and those of all breast, cervical, and squamous cell carcinomas examined readily supported complete Ad5 replication. The cells contained membrane-enclosed particles, and culture supernatants contained RNA particles with specific DNA polymerase activities. The normal embryonic, fetal, newborn, and adult cells also supported Ad replication.

Cell-free fluids of untreated or Ad-infected permissive human tumor and normal cell cultures had no DNA polymerase activities. Cell-free fluids of nonpermissive human tumor cells contained DNA polymerase activities at 3-9 days following Ad5 infection. The activation of detectable DNA polymerase-containing particles was dose- and time-dependent. Additional studies designed to label specifically the DNA and RNA in replicate cultures revealed that cell-free supernatants contained ³H-uridine-labeled particles with densities of 1.14-1.18 g/ml in equilibrium sucrose density gradients. DNA polymerase activities were detected within this range of density in fractions taken from these gradients. Heat-inactivated and antiserum-neutralized Ad5 did not infect or activate human tumor cells. The results suggest that infectious viruses with which humans normally have contact could, under proper host conditions, play a role in activating latent viruses associated with human tumors. (23 refs)

78-6968 **Defective Virions of Simian Adenovirus 7 Produced by One Passage at High Multiplicity of Infection.** (Eng) Price, J. A. (Dept. Microbiology, Univ. Massachusetts, Amherst, MA, 01003); Norkin, L. C. *Virology* 91(1): 194-197; 1978.

An assay for the rapid microtitration of simian adenovirus 7 (SA7) particles capable of inducing an adenovirus cytopathic effect (rounded, swollen cells) is described. Utilizing this assay for cytopathic particles, it was found that only one passage of standard SA7 at a high multiplicity of infection (moi) resulted in virus stocks containing an excess of noninfectious cytopathic particles. These stocks also contained an excess of defective virions that retained the ability to enhance the replication of human adenovirus type 5 during mixed infection of monkey cells. SA7 stocks produced on two simian virus 40-transformed simian cell lines contained larger fractions of these defective virions than stocks produced on normal cell lines. Autointerference activity was not observed in SA7 stocks containing an excess of defective cytopathic particles, and there were no detectable levels of shortened viral genomes. The results indicate that SA7 stocks containing an excess of defective particles are readily produced during only one passage at high moi. There need not be a drop in viral yields during subsequent passages to indicate that this phenomenon is occurring. (20 refs)

78-6969 **Phosphorylation of Chromatin- and Ribosome-associated Proteins in Cells Transformed by Adenovirus, Murine Sarcoma Virus, and Methylcholanthrene.** (Eng) Segawa, K. (Inst. Medical Science, Univ. Tokyo, Minato-ku, Tokyo 108, Japan); Oda, K.; Yuasa, Y.; Shiroki, K.; Shimojo, H. *J Virol* 27(3): 800-808; 1978.

The patterns of phosphorylation of chromatin- and ribosome-associated proteins in cells transformed by adenovirus

type 12 (Ad12), murine sarcoma virus (MSV), or methylcholanthrene (MC) were studied. A highly phosphorylated 90,000-dalton (90K) protein was detected in chromatin and ribosomes from Ad12-transformed WJ1, GY1, CY1, and WY3 cells; MSV-transformed H-NRK, K-BALB/3T3, and XC cells; MCA-transformed TCL15 mouse cells; and simian virus 40-transformed T22 monkey cells. The phosphorylated 90K protein was not detected in untransformed NRB, 3Y1, NRK, MV1Lu, or C3H.10T1/2 cells or in S+L-Mi mink cells transformed by Moloney MSV. The S+L-Mi cells showed rapid reversion to a normal morphology after several subcultures while continuing to contain rescuable MSV. The pattern of phosphorylation of proteins other than 90K in these cells resembled that of transformed rather than untransformed cells. Some 90K proteins became detectable in some untransformed cells that were stimulated to grow to the high density characteristic of transformed cells. Peptide map analysis indicated that the 90K protein of the transformed cells was similar irrespective of species of cell or transforming agent. The data suggest that the alteration in the pattern of endogenous protein phosphorylation in the chromatin and ribosomes is closely related to the transformed state of cells. (20 refs.)

- 78-6970 Characterization of Adenovirus Type 12 Tumour Antigen Produced in Chick Fibroblasts.** (Eng) Pusztai, R. (Inst. Microbiology, Univ. Medical Sch., H-6720 Szeged, Hungary); Tarodi, B.; Beladi, I. *J Gen Virol* 41(2): 433-436; 1978.

The type-specific tumor (T) antigen produced in adenovirus 12 (Ad12)-infected nonpermissive chick fibroblasts and permissive HEp-2 cells was characterized by immunoprecipitation with normal hamster serum and anti-T serum and sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The anti-T serum precipitated a polypeptide with an apparent mol wt of 50,000 and a smaller polypeptide of mol wt approx 11,000 from the infected HEp-2 and chick cells extracts. There was a considerably lower amount of the larger polypeptide in the chick cells than in the HEp-2 cells. These polypeptides were also obtained in the presence of 50 µg/ml cytosine arabinoside, but they were not observed when normal hamster serum was used or when mock-infected chick fibroblast extract was precipitated by anti-T serum. It is concluded that the size of the major component of Ad12-specific T antigen is 50,000 daltons. (8 refs)

- 78-6971 Poliovirus Single-stranded RNA and Double-stranded RNA: Differential Infectivity in Enucleate Cells.** (Eng) Detjen, B. M. (Dept. Biology, Washington Univ., St. Louis, MO, 63130); Lucas, J.; Wimmer, E. *J Virol* 27(3): 582-586; 1978.

The ability of single-stranded poliovirus virion RNA (PV-RNA) and double-stranded poliovirus replicative form

(RF) RNA to replicate in enucleated mouse L cells was investigated. Monolayers containing >99% enucleated L cells were prepared by cytochalasin B (10 µg/ml) treatment in conjunction with centrifugation. Control nucleate cells were prepared by similar treatment with cytochalasin B and omission of the centrifugation step. Virion RNA replicated successfully in the absence of the cell nucleus, but RF RNA did not produce any detectable progeny in enucleated cells. The results show that the nucleus is involved in RF RNA infection, presumably in the early stages. (47 refs)

- 78-6972 Poly(C)- and Poly(G)-rich Tracts in the RNA of Oncornaviruses.** (Eng) Phillips, L. A. (Lab. Viral Carcinogenesis, NCI, Bethesda, MD, 20014); Pang, R. H. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 311-319; 1977.

Evidence is given for the presence of poly(C)- and poly(G)-rich tracts in both untreated and RNase T₁- and RNase C-treated [dimethyl-³H] viral RNA of avian, murine, hamster, feline, and primate oncornaviruses (OV's) as detected by polynucleotide agarose affinity columns. This finding demonstrates the universality of these tracts in the RNA of leukemia and sarcoma viruses. The tracts may play a genomic stabilizing role in OV RNA, and they may also play a role in the transcription of OV RNA. Poly(C) may be involved in the replication of some other viruses, as encephalomyocarditis virus-infected cells contain a viral specific polymerase that can use poly(C) homopolymers as templates, and poly(C) homopolymers can also serve as templates for Q β replicase. If it can be determined that OV RNA contains specific polynucleotide sequences or tracts that are not present in nonviral messenger RNA (mRNA) of human cells, it may be possible to make sequence-specific drugs against the unique viral-specific polynucleotide sequences or tracts to block transcription of viral RNA into viral DNA by reverse transcriptase and to block translation of viral RNA into viral proteins by the cellular ribosomes, while not affecting the translation of cellular nonviral mRNA into cellular proteins. Thus, a possible molecular approach to cancer therapy may become a reality. (27 refs)

- 78-6973 DNA Polymerase Reactions in Human Bladder Tumor Cells in Culture: Characterization of the RNA-associated Product.** (Eng) Davis, A. R. (Dept. Microbiology and Immunology, Univ. California Sch. Medicine, Los Angeles, CA, 90024); Vayuvegula, B. S.; Nayak, D. P. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Preven-

and Detection of Cancer (New York, NY): Vol. 1(part 193 pp.; 17-26; 1977.

RNAse-sensitive endogenous DNA polymerase activity in the cytoplasmic pellet fraction of cultured T-24 derived from a human transitional cell carcinoma of the bladder was partially characterized. Pretreatment of the cytoplasmic pellet with RNAse reduced the activity threefold, and the reaction was inhibited 80% by actinomycin D (AD). The reaction kinetics were linear for 5 min only. Analysis of the DNA product of 5-min reactions, prepared in the presence of Cs₂SO₄, by equilibrium-density gradient centrifugation revealed a nucleic acid product migrating as 10%-47% RNA (density 1.63) and 30%-70% DNA (density 1.39-1.42). Less than 1% of the product prepared under the same conditions from T-24 nuclei or mitochondria or from the cytoplasmic fraction of WI-38 cells, a normal human diploid cell line, migrated as RNA. The label in the RNA region of the gradients no longer migrated as RNA after treatment with the total product with high- and low-salt RNAse or S-1 nuclease. Under conditions in which hybrids are maintained with high-salt RNAse or S-1 nuclease, small amounts of material were seen migrating in the hybrid region of the gradients. The ³H-DNA recovered from the RNA region of the gradients was partially resistant to S-1 nuclease. Thus, part of the RNA-associated DNA product was a RNA-DNA hybrid and part was single-stranded DNA. Known RNA tumor viruses catalyze the transcription of RNA to DNA via reverse transcriptase, with early products being RNA-DNA hybrids. The DNA polymerase reaction product migrating as DNA and other properties of the reaction indicate that reverse transcriptase is present in the T-24 cells. (31 refs)

6974 **Ultrastructural Study of Virus-like Particles in Chinese Hamster Lung Cells.** (Eng) Calafat, J. (Dept. Virology, The Netherlands Cancer Institute, 108 Saristraat, Amsterdam, Netherlands); Hilken, J. G. *J Gen Virol* 41(2): 417-420; 1978.

Virus-like particles found in the E36 cell line derived from Chinese hamster lung cells are described. Two kinds of particles were found: viruslike particles in the cytoplasm associated with the centrioles, and extracellular viruslike particles resembling the immature and mature forms of the oncornaviruses but different from the classical B- and C-type particles. Apparently, the intracytoplasmic, budding, immature, and mature particles noted were different stages in the morphogenesis of the same virus. No major C- or B-type virus proteins were detected, indicating that there was no immunological relationship between the virus characterized and the oncornavirus from mammals or mouse B-type virus. (12 refs)

6975 **Transformation of Normal Bone-Marrow Cells by a Leukaemic Cell Line Associated with a**

Presumptive New Human Virus. (Eng) Karpas, A. (Dept. Haematological Medicine, Univ. Cambridge Clinical Sch., Hills Road, Cambridge, England); Wreghitt, T. G.; Nagington, J. *Lancet* 2(8098): 1016-1019; 1978.

Experiments were carried out to determine whether the intracytoplasmic leukoviruslike bodies found in the cells and culture medium of a T-cell lymphoblast line established from a leukemic patient could transform normal human bone marrow cells in vitro. The leukemic cell line (241 cells) was initiated from the buffy coat of a man with terminal acute monocytic leukemia superimposed on a longstanding non-Hodgkin's lymphoma. When the cells were lethally irradiated and added to normal bone marrow cells from a female donor, the latter were transformed into continuous replication, and they produced the same types of viruslike particles. The new cell line (P2-241), which has been in continuous culture for 4 mo, consists of female B lymphoblasts quite distinct from the male T-cell line 241. Sectioned cells of the nonirradiated line 241 and marrow line P2-241 contained two types of round viruslike particle in the Golgi region, one approx 50 nanometers (nm) and the other 70 nm in diameter. Formation of 50-nm particles by intracytoplasmic budding was observed. It appears that marrow cells are transformed in vitro to continuous replication by the 241 cell line. (10 refs)

78-6976 **Reverse Transcriptase Activity in Extracts of Human Prostatic Tissues.** (Eng) Job, L. (Dept. Medical Viral Oncology, Roswell Park Memorial Inst., Buffalo, NY); Carter, W. A.; Arya, S. K. *Oncology* 35(5): 202-205; 1978.

Three types of human prostatic tissue (normal, hyperplastic, and adenocarcinoma) were examined for particle-associated reverse transcriptase (RT) activity. The activity was isolated by banding the tissue extract in an equilibrium sucrose density gradient followed by phosphocellulose chromatography of the lysate of material banding at 1.14-1.20 g/ml. It was characterized by its utilization of poly(Cm), which is a specific template for oncornaviral RT, and by its inhibition by selective inhibitors of viral RT, such as poly(Am) and poly(I). The activity did not utilize synthetic DNA templates, such as poly(dA):oligo(dT) and poly[d(A-T)], which is consistent with the interpretation that the DNA polymerase activity isolated from prostatic tissue is a RT. Of the tissues examined, 1/4 normal, 5/6 hyperplastic, and 2/2 adenocarcinoma specimens contained viruslike RT activity. These results suggest that oncornaviruses may be associated with the human prostate. (18 refs)

78-6977 **Inclusion Bodies Containing Virus-like Particles in Acute Lymphocytic Leukaemia of Childhood.** (Eng) Smith, H. (Dept. Pathology, Royal Brisbane Hosp., Queensland 4029, Australia). *Leuk Res* 2(2): 133-140; 1978.

Lymphoid cells from 28 children with acute lymphocytic leukemia (ALL) and from three control groups (children with acute nonlymphocytic leukemia or nonleukemic malignancies and normal children) were examined for the presence of distinctive cytoplasmic inclusions. Light microscopy revealed such inclusions (0.7-7.6 μm) in 12/28 ALL patients. The inclusions tended to be close to the nucleus or were attached to it by a stalk. Inclusions were not seen in nonlymphoid cells; they were more frequent in leukemic than in nonleukemic lymphocytes, and more frequent in marrow than in blood cells. In all other patients with inclusions, they were found only in leukemic cells. Inclusions were more frequent in necrobiotic cells than in viable lymphoid cells in blood but not marrow of one patient. Electron microscopy showed that the inclusions are enclosed particles with a membrane usually 10-30 nanometers (nm) thick but in some cases up to 100 nm thick. Budding from the inside of the enclosing membrane was suggested by connection between it and some particles and by clustering of particles around some villi. Inclusions similar to those in ALL were seen rarely in normal lymphocytes and in acute nonlymphocytic leukemic cells, but they were seen often in nonleukemic malignancies. Profusely populated groups (≥ 20 particles in a profile) and villous intrusions of the enclosing membrane occurred only in the ALL

patients. The particles do not resemble known viruses, but some characteristics suggest that they have a viral nature. (23 refs)

IMMUNOLOGY

5978 **A Serum Inhibitor of Cell Mediated Immunological Functions in Healthy Mice and Possible Relations with C-Type Viral Expression and Spontaneous Plasmia.** (Eng) Krueger, J. G. (Thorman Cancer Res. Lab., City Univ., San Antonio, TX, 78284); Moyer, R. C. *In: 3rd International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1 (part 1) 193 pp.; 409-427; 1977.

... suggesting the presence of an inhibitor of cell-mediated immunological functions in the serum of healthy DBA/2J mice possessing latent C-type leukemia virus are presented. The phytohemagglutinin responsiveness (PHAR) of peritoneal lymphocytes in a whole blood culture was measured. ³H-thymidine uptake in nine inbred strains of mice. High PHAR was seen in different strains, even though lymphocytes were taken from 14-wk-old sex-matched mice. High responders showed no C-type virus expression; mice of the low responder strains showed C-type virus expression throughout their lives. The low PHAR of these strains was investigated further using low-responder DBA/2J mice plus high-responder C57BL/6J mice for comparison. Low responsiveness of DBA/2J mice was not related to dose-response factor, to a time shift in response to PHA, to age. Splenic lymphocytes showed good PHAR, ruling out the possibility of an intrinsic cellular defect. Low responder serum reduced the PHAR of syngeneic splenic lymphocytes, and splenic lymphocytes failed to incorporate PHA actively in the presence of this serum. C57BL/6J mice showed no significant inhibiting effect on allogeneic syngeneic lymphocytes. C57BL/6J serum increased the response of C57BL/6J splenic lymphocytes to tumor-associated antigens from a syngeneic mammary carcinoma by 100%. DBA/2J serum prevented the response of DBA/2J splenic lymphocytes to syngeneic tumor-associated antigens. Ability of lymphocytes to perform cell-mediated functions may be inhibited by factors in the serum of healthy mice. (22 refs)

5979 **Influence of a Mixture of Chemical Protectors on the Lymphoid Regeneration of Bone Marrow and Thymus in Irradiated Mice.** (Eng) Delrez, M. (Laboratoire d'Anatomie Pathologique, Institut de Pathologie, Université de Liege, B-4000 Liege, Belgium). *Experientia* 34(9): 1122-1222; 1978.

... effect of chemical radioprotectors on the lymphoid peak in bone marrow and on the thymic cell population was deter-

mined in female C57BL mice. At 25 min before x-irradiation (400 or 650 R), the mice received 15 mg glutathione po; 10 min later, they received 8.5 mg cysteine ip followed 5 min later by ip injection of a mixture of 1.4 mg 2-β-aminoethylthiouronium, 3 mg cysteamine, and 0.65 mg 5-hydroxytryptamine. Administration of the chemical protectors without subsequent irradiation had little effect on the bone marrow but induced a significant decrease in thymocyte number. Administration of the protectors before irradiation permitted a better bone marrow repopulation and reduced late thymic atrophy (a condition that precedes the appearance of thymic lymphomas), compared with the effects of the radiation in nonprotected animals. The lymphoid peak was considerably increased in the radioprotected animals. Thus, under conditions that were previously shown to reduce the development of lymphomas, a lymphoid rebound appeared in the bone marrow. (8 refs)

78-6980 **Electronic Cell Volume Analysis of Growth and Rejection of EL-4 Ascites Tumor Cells.** (Eng) Zucker, R. M. (Papanicolaou Cancer Res. Inst., P.O. Box 236188, Miami, FL, 33123); Harari, J.; Finley, J.; Kambour, M. *Am J Vet Res* 39(10): 1710-1712; 1978.

The in vivo growth of EL-4 leukemia cells in the peritoneal cavities of syngeneic (C57BL/6) and allogeneic (DBA/2) mice was monitored daily by electronic cell volume and cell number analysis, cell morphology, and labeling index. In C57BL/6 mice, tumor cell number increased from 2×10^5 to 8×10^5 , cell volume decreased from 440 to 360 μm^3 , and the labeling index decreased from 57% to 20% from days 5 to 9 after inoculation. The volume decrease was correlated with an increased cell cycle time and a decreased proliferating fraction. During the later stages (10-15 days) of EL-4 ascites tumor growth in these mice, the cell number remained constant but the cells continued to grow and divide. In DBA/2 mice, rejection of tumor cells began on day 7 after inoculation; cell number decreased from 4.6×10^5 to 2.5×10^5 cells, modal population volume from 370 to 355 μm^3 . The degree of rejection was determined by electronic index; these variables were not uniform among the mice. Concomitant with the decrease in cell number and labeling index seen between days 7 and 8, the number of lymphocytes, macrophages, and dead tumor cells increased. The size of the lymphocytes was 240 μm^3 , and that of the macrophages and dead tumor cells was 640-1,280 μm^3 . Lymphocyte volume decreased during the rejection process until it was 110 μm^3 at complete rejection. These results demonstrate that electronic cell volume analysis can be used to study the influx of different cell types during the rejection as well as the growth of tumor cells. (12 refs)

78-6981 Complete Tumor Inhibition by a Physiological Factor in Cell-Free Tumour Ascites. (Eng)

Kapp, J. F. (Schering AG, Research Labs., Mullerstrasse 170, 1000 Berlin 65, W. Germany). In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society. Symposium held in Edinburgh, September 12-14th, 1977.* Univ. Edinburgh. (Edinburgh, Scotland): pp. 285-291; 1977.

Anti-inflammatory activity was demonstrated in mouse and rat cell-free tumor ascites fluids. Ascites from Ehrlich (including diploid and tetraploid), L1210, Krebs, and Yoshida mouse tumors and from Yoshida hepatoma, Yoshida sarcoma, and Zajdela hepatoma rat tumors were tested in the carrageenan NMRJ mouse paw edema test. Mouse tumor ascites inhibited the inflammation reaction from 40.5% to 58.5%, rat tumor ascites from 28% to 45%, but normal sera from either species were inactive. There were no inflammatory cells in the site of the inflammatory stimulus. With respect to antitumor activity, tumor growth was inhibited completely when 1 ml tumor ascites was injected ip 24 hr before ip injection of 1×10^5 tumor cells. An inoculum of 3×10^5 DBA/1J mammary adenocarcinoma cells injected sc into NMRJ mice and grown to 5 mm in diameter underwent continuous regression when 1 ml L1210 ascites fluid was injected. Likewise, human HeLa cells (1×10^5) injected ip into nu/nu mice were inhibited by injection of the mice with 1 ml Yoshida ascites 24 hr previously, demonstrating interspecies protection. Because sensitized lymphocytes from spleens and lymph nodes did not demonstrate cytotoxic activity in a ^{51}Cr -release assay, inhibition of tumor growth apparently occurs by stimulation of nonspecific host defense mechanisms. (9 refs)

78-6982 Anti-viral Activity Induced by Culturing Lymphocytes with Tumor-derived or Virus-transformed Cells. Identification of the Anti-viral Activity as Interferon and Characterization of the Human Effector Lymphocyte Subpopulation. (Eng) Trinchieri, G. (Swiss Inst. Experimental Cancer Res., Epalinges, CH 1066, Switzerland); Santoli, D.; Dee, R. R.; Knowles, B. B. *J Exp Med* 147(5): 1299-1313; 1978.

The viral inhibitor(s) released in the supernates of mixed cultures of mouse or human lymphocytes and certain tumor-derived or virus-transformed mouse or human cell cultures was characterized. The inhibitor thus induced proved to be a protein that was active against a variety of unrelated viruses and was not toxic for cells. It did not directly inactivate viruses but inhibited viral replication via an intracellular mechanism that involved RNA and protein synthesis by the cells. The inhibitor was identified as interferon, which was contained in at least two molecular species, of approx 25,000 and 45,000 daltons, respectively. The supernates of the mixed cultures also displayed an anticellular activity and an ability to inhibit DNA synthesis and cell multiplication. The antiviral and anticellular activities were positively correlated in supernates from various mixed cultures and in partially purified

preparations. The human cell population involved in interferon production was composed primarily of Fc receptor-positive, surface immunoglobulin negative, non-T-cell lymphocytes. The ability of certain cell lines to induce interferon was significantly associated with tumor origin or with in vitro transformation by certain viruses (Epstein-Barr virus, murine sarcoma virus). (56 refs)

78-6983 Anti-viral Activity Induced by Culturing Lymphocytes with Tumor-derived or Virus-transformed Cells. Enhancement of Human Natural Killer Cell Activity by Interferon and Antagonistic Inhibition of Susceptibility of Target Cells to Lysis. (Eng) Trinchieri, G. (Swiss Inst. Experimental Cancer Res., Epalinges, CH 1066, Switzerland); Santoli, D. *J Exp Med* 147(5): 1314-1333; 1978.

The effects of the interferon produced in mixed cultures of human lymphocytes and human tumor-derived or virus-transformed lines on the two cell populations were studied. Interferon preparation increased by severalfold the nonspecific cytotoxicity of human lymphocytes, the effector cells being cytotoxic for any target cell line tested and the enhanced cytotoxicity lasting for 2-3 days. The activity of spontaneous (natural) killer lymphocytes was not separable from the cytotoxic activity induced by the interferon preparations, suggesting that the interferon enhanced the activity of the natural killer cells rather than generating a new population of effector cells. In the mixed cell cultures in which interferon was produced, the interferon mediated an enhanced cytotoxicity representing up to 70%-90% of the observed cytotoxicity. The effect of interferon on the target cells was antagonistic to its effect on the lymphocytes, the susceptibility of various cells to cell-mediated lysis being decreased and in some cases almost completely suppressed after pretreatment with interferon. Interferon rendered target cells resistant to natural killer cells via an intracellular mechanism requiring RNA and protein synthesis. Virus-infected cells and most tumor cells were not similarly protected by interferon. It is suggested that interferon might render the natural killer cell system an inducible selective defense mechanism against tumor and virus-infected cells. This might occur by stimulation of efficient nonspecific cytotoxic cells and by protection of normal cells from lysis. (56 refs)

78-6984 Increases and Perturbations in Thymocytes Forming Spontaneous Rosettes During Viral and Chemical Oncogenesis in Hamsters. (Eng) Leffell, M. S. (Clinical Micro Lab., North Carolina Memorial Hosp., Univ. North Carolina, Chapel Hill, NC, 27514); Coggin, J. H. *Clin Immunol Immunopathol* 11(3): 275-287; 1978.

Because spontaneous (E) rosette formation with sheep RBC has been linked to diseases that involve deficient cellular immunity including malignancies, thymocytes from strain LVG Syrian golden hamsters were tested for their ability to form

rosettes with sheep RBC. Preliminary studies revealed an unusual seasonal variation in the percentage of rosette-forming cells (RFC) (17.2% formation in winter, compared with 10.5% in later summer and fall). Further studies showed that, regardless of the seasonal variation, the number of RFC increased during viral and chemical carcinogenesis. Infection of neonate hamsters with simian virus 40 or adenovirus 13 resulted in a 50% or greater increase in RFC in thymuses of individual hamsters assayed as early as a 2 wk postinfection. Treatment of weanling hamsters with dimethylbenzanthracene resulted in significant increases in thymocyte RFC at the time of primary sarcoma appearance. The carcinogen-induced RFC increases appeared to be limited to a small subset of thymocytes that reacted in dextran-containing medium, compared with a larger population that bound sheep RBC in the presence of heat-inactivated, sheep RBC-absorbed serum. In the thymocyte subset, the increases in RFC were most marked after primary tumor induction. Passively transferred tumor cells had only a slight effect on RFC values. (19 refs)

78-6985 Immune Response of the Syrian Golden Hamster to SV40 Induced and Transplantable Tumors. (Eng) Goldrosen, M. H. (Dept. Surgical Oncology, Tumor Immunology Group, Roswell Park Memorial Inst., Buffalo, NY, 14263); Dent, P. B. *Fed Proc* 37(7): 2092-2095; 1978.

The effector mechanisms that are operative against the growth of simian virus 40 (SV40)-induced tumors were investigated. Cell-mediated immunity of progressor, postexcision, and immune peripheral blood lymphocytes was evaluated in vivo by the lymphocytotoxicity assay. At a ratio of 200:1, three types of peripheral blood lymphocytes caused a significant reduction in the number of H50 (SV40-transformed) target cells but did not reduce the number of hamster fibroblasts. No significant cytotoxicity was observed with these effector populations on BHK-21 cells, which do not carry SV40-associated antigens. Thus, cytolytic effector cells can be detected at all phases of progressive tumor growth and at all stages of tumorigenesis evaluated. However, the presence of these cells may not reflect functional in vivo tumor rejection. The effects of the three sera on in vitro lymphocytotoxicity were also investigated. The only situation in which serum blocking factors were noted was in animals that experienced a recurrence of a previously excised tumor. Serum blocking factors were not present in the early and middle stages of progressive tumor growth; therefore, they could not be an important factor in the critical early stages of tumor growth. Serum taken from hamsters shortly after inoculation with H50 cells but before the clinical appearance of the tumor demonstrated characteristics similar to those of serum taken from immunized hamsters. These sera augmented the cytotoxic reactivity of tumor immune lymphocytes in vitro and did not induce normal lymphocytes to specifically kill tumor cells. These findings suggest that progressive primary tumor growth may be due to a lack of serum arming and potentiating

activity rather than the presence of serum blocking factors. On the other hand, serum blocking factors may correlate with the presence of recurrent or metastatic disease rather than with progressive tumor growth alone. (25 refs)

78-6986 Studies of Effector Cell, Antibody, and Target Cell Interactions in Natural Cell-mediated Cytotoxicity. (Eng) Koide, Y. (Dept. Surgery, UCLA Sch. of Medicine, Univ. California, Los Angeles, CA, 90024); Kwok, R.; Takasugi, M. *Int J Cancer* 22(5): 546-551; 1978.

IgG antibodies bound to effector lymphocytes obtained from human peripheral blood through Fc receptors were observed to determine the specificity of natural cell-mediated cytotoxicity (NMC) against cultured target cells, including sheep RBC (SRBC), antilymphocyte serum-treated lymphocytes, and a lymphoblastoid cell line. When effector cells, which possessed natural antibodies specific for antigens on cultured cells but lacked IgG antibodies specific for antigens on SRBC, were incubated in IgG anti-SRBC, they became specifically cytotoxic to SRBC. As a result of this gained specific cytotoxicity, NMC and antibody-dependent CMC was diminished, suggesting that natural antibodies were displaced and Fc receptors on effector cells occupied by IgG anti-SRBC. It is concluded that treatment of effector cells with serum may result in increased or decreased cytotoxicity, depending upon the serum composition of specific antibodies. This type of modulation has important implications for antibody regulation of CMC (blocking and unblocking). (23 refs)

78-6987 Spontaneous and Antibody-dependent Cell-mediated Cytotoxicity by Human T Cell Subpopulations. (Eng) Gupta, S. (Memorial Sloan-Kettering Cancer Center, New York, NY, 10021); Fernandes, G.; Nair, M.; Good, R. A. *Proc Natl Acad Sci USA* 75(10): 5137-5141; 1978.

Human peripheral blood non-T cells, T cells, and their subpopulations (T_{μ} , T_{γ} , T_{ϕ} , T_{γ} -depleted cells, and T_{μ} -depleted cells) were assayed for their ability to mediate spontaneous lymphocyte-mediated cytotoxicity (SLMC) against K562 tumor cells and antibody-dependent cellular cytotoxicity (ADCC) against chicken RBC coated with antibody. (T_{μ} = T cells with receptors for IgM; T_{γ} = T cells with receptors for IgG; T_{ϕ} = T cells without receptors for IgM or IgG.) Non-T cells and purified T cells mediated both ADCC and SLMC. Depletion of T_{μ} cells did not influence these activities, whereas depletion of T_{γ} cells resulted in almost complete loss of both activities. Isolated T_{μ} cells and T_{ϕ} cells did not demonstrate significant ADCC or SLMC activity, and T_{γ} cells demonstrated strong SLMC activity but did not demonstrate significant ADCC activity. The data demonstrate that SLMC and ADCC activities in T lymphocytes are mediated by T_{γ} cell subpopulations. The two cytotoxic reactions may be mediated by two distinct subsets of T_{γ} cells or by a single effector cell type using two different mechanisms. (54 refs)

- 78-6988 Cytotoxic Activity of Guinea-Pig Lymph-Node Cells Stimulated In Vitro.** (Eng) Altman, A. (Dept. Cellular and Developmental Immunology, Scripps Clinic and Res. Foundation, 10666 N. Torrey Pines Road, La Jolla, CA, 92037); Rapp, H. J. *Int J Cancer* 22(5): 595-601; 1978.

Several stimulators of lymphocyte proliferation were tested for their capacity to induce strain 13 guinea pig lymph node cells (LNC) to become cytotoxic in vitro. The stimulating agents were 5% fetal calf serum; 5×10^5 M 2-mercaptoethanol; 1.6×10^5 virally induced, syngeneic, 543 sarcoma cells or various amounts of allogeneic (strain 2) mineral oil-induced peritoneal exudate cells, all treated with 60 μ g/ml mitomycin C; and 2.5 μ g/ml phytohemagglutinin (PHA) or concanavalin A. LNC cultured in the presence of these agents were cytotoxic to normal syngeneic fibroblasts and to syngeneic, (13F, 543), allogeneic (L1), or xenogeneic (human myeloid line K562) tumor cells, but not the PHA-induced strain 2 lymphoblasts. LNC had weak or no cytotoxic activity when freshly harvested from guinea pigs, indicating that acquisition of cytotoxicity was a result of events occurring in culture. Potentiation of cytotoxicity was accompanied by a marked proliferation of the cultured LNC; the combination of several stimulatory agents had an additive effect on the generation of cytotoxicity. (20 refs)

- 78-6989 Production of Migration Inhibitory Factor (MIF) by Human Leukocytes Following Exposure to Epstein-Barr Virus.** (Eng) Wilson, G. L. (Dept. Microbiology, Univ. Maryland, College Park, MD, 20742); Young, B. G. *Cell Immunol* 38(1): 147-156; 1978.

The ability of Epstein-Barr virus (EBV) to induce a cell-mediated immune response (CMI) in cultures of human WBC was investigated. Partially purified EBV, obtained from culture fluids of AV-1 cells, was inactivated by exposure to UV radiation. Inactivated virus was mixed with peripheral WBC from Hodgkin's disease (HD), infectious mononucleosis (IM), and malignant lymphoma patients as well as from normal individuals. Production of migration inhibitory factor (MIF), as measured by guinea pig macrophage migration inhibition (MMI), was used as an indicator of CMI response. Significant differences in MIF response were observed subsequent to exposure of the cells to EBV. WBC from patients in each of the disease categories tested exhibited greater MIF production than WBC from normal controls. Furthermore, there was a significant difference between the response of IM-derived cells and the response of HD- and lymphoma-derived cells. Serum from each subject was examined for immunoglobulin specific for EBV capsid antigen (anti-VCA). Although the majority of individuals within the disease categories tested had elevated anti-EBV serum titers, no correlation could be made between elevated anti-VCA titer and levels of MIF production. Abstract). (Eng) Freedman, V. H. (Rockefeller Univ., New York, NY); Calvelli, T. A.; Silagi, S.; Silverstein, S. C. *J Cell Biol* 79(2, part 2): 91a; 1978. (no refs)

- 78-6991 Do Tumors Escape Surveillance by Depression of Macrophage Inflammation?** (Eng) Norman, S. J. (Dept. Pathology, Univ. Florida Coll. Medicine, Gainesville, FL, 32610); Scharadt, M.; Sorkin, E. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 247-257; 1977.

The hypothesis that growing tumors compromise monocyte chemotaxis and decrease macrophage (MP) accumulation in inflammatory foci, thereby altering the ratio of MP to tumor cells, decreasing the probability for close contact of these cells, and escaping growth control by MP, was investigated. Nitrocellulose filter disks were inserted into the connective tissue of DA rats with and without transplanted 7,12-dimethylbenz(a)anthracene (DMBA)-induced tumors. Twelve days after transplantation, both groups showed a biphasic pattern of MP accumulation, but in tumor-bearers both the total number of cells and their rate of accumulation were diminished markedly. This depression in MP accumulation was approx 65% and it lasted for at least 5 days, despite the persistence of the inflammatory stimulus. Thus, tumor-bearing induced a generalized defect in MP inflammation by altering MP accumulation not only in the peritoneal cavity but also in inflamed connective tissue. The defect required the continued presence of the tumor, as it was rapidly corrected by surgical excision of the primary tumor. However, the defect usually occurred late in tumor growth, required a threshold number of tumor cells often exceeding 100 million, and did not exist when the animal possessed latent tumor cells that remained viable following surgical resection of the primary tumor. Thus, it is concluded that the defect in monocyte inflammation arises as a result of neoplastic progression and that it is not a factor that limits surveillance or contributes to the emergence of nascent cancer cells. (27 refs)

- 78-6992 Inflammation and Activation of Macrophage** (Eng) Fauve, R. M. (Unite d'Immunophysiologie Cellulaire, Institut Pasteur, 25 Rue du Dr. Roux, 7501 Paris, France); Hevin, M. B.; Dauge, M. C. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 258-263; 1977.

C57Bl mice were highly resistant to challenge with virulent *Listeria monocytogenes*, *Schistosoma mansoni*, and the Lewis lung carcinoma (LLC) when inflammatory reactions were induced previously at a distance from the site of infection by injecting the dorsal area sc with magnesium silicate embedded in calcium phosphate gel. When *L. monocytogenes* was

ected iv (10 LD₅₀), mice with the inflammation had 10³ and less organisms in spleen and liver on the third day than control mice. Similarly, mice with an inflammatory reaction are free of worms 45 days postinfection with 100 furcocercariae of *S. mansoni*. When 10⁶ LLC cells were injected into the rear left footpad 4 days before or 4 days after induction of the inflammatory reaction, tumor growth was delayed. No metastases were found in the lungs of treated mice 20 days after LLC inoculation. When mice received 10⁶ LLC cells in the sternal area one day before inflammation induction, metastases were delayed and there were many WBC and macrophages among the tumor cells. These results suggest that some sort of serum mediator acted on the pathogens, since these were never in physical contact with the inflammatory reaction. (10 refs)

6-6993 **Regulation of Macrophage Tumoricidal Function: A Role for Prostaglandins of the E Series.** (Eng) Schultz, R. M. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Pavlidis, N. A.; Stylos, W. A.; Chirigos, M. A. *Science* 202(4365): 320-321; 1978.

The ability of several agents to interfere with macrophage activation by interferon (IF) preparations in vitro was measured using macrophages from male CD2F₁ mice. IF (1,000 units/ml culture medium) was added to the macrophage cultures for 16 hr. Agents tested for inhibitory action were added in 100-μl portions. Treated macrophages were tested for cytotoxicity to MBL-2 lymphoblastic leukemia cells. IF-activated macrophages suppressed leukemia cell growth at 48 hr by 67%. When prostaglandin E₁ or E₂ was added simultaneously with IF to resting macrophages or for 2 hr after treatment, the tumoricidal activity of the macrophages was inhibited. A prostaglandin concentration of > 10⁻⁷ M was necessary for macrophage suppression. Prostaglandin F₂ was ineffective at all concentrations tested when added simultaneously or after IF treatment. Dibutyl cyclic AMP and hydrocortisone also decreased macrophage tumoricidal activity. Subsequent treatment of IF-activated macrophages with dibutyl guanosine 3',5'-monophosphate (GMP), indomethacin, or colchicine did not influence macrophage tumoricidal function. The regulation of macrophage function by IF and prostaglandin E may occur through a balance in cyclic AMP- and cyclic GMP-associated signals. Direct evidence for this conclusion awaits corroboration of levels of cyclic nucleotides in the macrophages with the observed effects of the agents tested. (22 refs)

6-6994 **Striking Differences in Interaction Between Macrophages and Two Closely Related Tumor Lines.** (Eng) Kaplan, G. (Dept. Morphology, Inst. Medical Biology, Tromsø, Norway); Seljelid, R. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 347-363; 1977.

A murine methylcholanthrene-induced solid sarcoma (MSS), its ascites form (MAA), and a solid tumor line derived from it (MAS) were used to study the in vitro interaction of syngeneic mouse macrophages with the tumor cells from intraperitoneal transfers. After sc or ip injection into C₃H mice or their F₁ hybrids, MSS cells yielded solid tumors which metastasized efficiently. MAS cells injected sc yielded solid tumors and injected ip yielded nonmetastasizing ascites when injected ip. Ascites from the mice which developed them were grown in culture. Macrophages from the MAA cultures became activated as indicated by their morphology and ability to ingest complement-coated particles. The macrophages proliferated and inhibited tumor cell growth; macrophage proliferation then decreased as the tumor cells died. The presence of tumor cells was apparently required for macrophage activation, and the macrophages appeared to kill the tumor cells by nonphagocytic means. The MAS cells showed less macrophage activation, and tumor cell killing was not apparent. The data show a correlation between the ability of tumor cells to give rise to solid metastasizing tumors and the extent to which the tumor could be inhibited and killed in vitro by syngeneic macrophages; ie, the more aggressive tumor in vivo is less susceptible to macrophage activation and killing in vitro. (30 refs)

78-6995 **Antitumour Effects of Macrophages in BCG Contact Therapy of Rat Tumours.** (Eng) Hopper, D. G. (Cancer Res. Campaign Labs., Univ. Nottingham, Nottingham, England); Pimm, M. V. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* Univ. Edinburgh. (Edinburgh, Scotland): pp. 182-187; 1977.

Wistar/Nottingham rats were inoculated sc with 2 x 10⁶ sarcoma Mc7 or Mc40A cells or hepatoma D23 cells, alone or in admixture with 1 mg BCG, and the cellular contents of the resulting tumors were investigated. Sarcoma cells alone produced progressively growing tumors, and the sarcoma cell: macrophage (MP) ratio was 1:0.2 for the Mc7 cells at 22 days and 1:0.4 for the Mc40A cells at 17 days. BCG + sarcoma cells, however, produced small nodular resector tumors, and the ratios were 1:1.3 for the Mc7 cells at 22 days and 1:1.0 for the Mc40A cells at 17 days. Lymphocyte levels were similar in regressor and progressor tumors. Hepatoma D23 was not as susceptible to BCG contact therapy as the sarcomas. BCG + hepatoma cells produced tumors whose growth was progressive although retarded compared to that of tumors developing from injection of hepatoma cells alone. The hepatoma cell:MP ratio in the BCG-progressor tumors was 1:0.3 at 6 days; that in the progressor tumors developing from tumor cells injected alone was 1:0.1. These results suggest that for BCG to prevent the growth of 2 x 10⁶ tumor cells, sufficient MP must be present at the tumor site. This hypothesis is strengthened by the results of experiments in which the hepatoma cell-BCG inocula was enriched with 50% MP. An increase in MP numbers to the extent that the

hepatoma cell:MP ratio was 1:1 rendered the tumor cells susceptible to BCG contact therapy; ie, it prevented their growth completely. (33 refs)

- 78-6996 Stimulation of Tumor Growth in Mice by High Doses of BCG.** (Eng) Kaledin, V. I. (Inst. Cytology and Genetics, Siberian Dept. USSR Acad Sciences, Novosibirsk, 90, USSR); Kurunov, Y. N.; Matienko, N. A.; Nikolov, V. P. *J Natl Cancer Inst* 61(6): 1393-1396; 1978.

The effect of BCG vaccination on the growth of Krebs-2 carcinoma was studied in virgin female C57BL/6 (susceptible to BCG infection), CC57BR/M (resistant to BCG), and C3Hf (resistant to BCG, mammary tumor virus-free) mice. Animals were vaccinated at 2 mo of age with 0.05 mg live BCG. Thirty days later, 1 or 2 x 10⁵ Krebs-2 carcinoma cells were injected im and the animals killed 15 days later. The number of living BCG in C57BL/6 mice was 30 times higher than that in C3Hf mice, and the tumors in vaccinated C57BL/6 mice were 1.5 times heavier than those in control C57BL/6 mice. The tumor wt of BCG-vaccinated and control C3Hf mice did not differ, indicating that tumor growth was stimulated only in the BCG-sensitive strain. Various doses of BCG were given to C57BL/6 and CC57BR/M mice 14 days prior to Krebs-2 transplantation. When the BCG dose was sufficiently high (1.0 mg), tumor growth was stimulated in both mouse groups. Dead mycobacteria and inert particles (India ink) promoted tumor growth, suggesting that this effect may be due to the presence of large quantities of corpuscular particles which load the macrophages and render them incapable of guarding against the transplanted tumor cells. When Krebs-2 carcinoma was transplanted in CC57BR/M mice 80 days after BCG vaccination (when no viable BCG were detected in the spleen), tumor growth was inhibited 41.5%. These results indicate that the effects of BCG are based on the diversion of effector cells (macrophages) and on the activation of pools of these cells. High doses of BCG may be dangerous in human cancer immunotherapy, and patients predisposed to cancer should be revaccinated with BCG to maintain the effector cell pool at a high level of activation. (18 refs)

- 78-6997 The Effect of the Macrophage Cytotoxic Agent Iota Carrageenan on the Growth of Two Transplantable Murine Ascites Tumours.** (Eng) Pugh-Humphreys, R. G. (Dept. Zoology, Univ. Aberdeen, Tillydrone Ave., Aberdeen AB9 2TN, Scotland); Richardson, C. A.; Wilson, A. R.; Cruickshank, W. J. *In: The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 142-154; 1977.

The role of macrophages (MP) in the growth of ascites tumor allografts in C57BL10 mice was evaluated with the use of a

commercial preparation of the MP cytotoxic agent iota carrageenan (IC: Auby Gel X52). Groups of 10 mice were inoculated ip with 10 µg IC 24 hr before they were inoculated ip with threshold or subthreshold doses of Landschutz ascite carcinoma (LAC) or EL4 ascites lymphoma cells. In preliminary experiments, light and electron microscope studies of aspirated lymphoreticular cells at varying times after ip injection of IC alone revealed that IC was selectively cytotoxic for peritoneal MP but not for lymphocytes or polymorphonuclear WBC. Injection of the tumor cells alone elicited an inflammatory response within the peritoneal cavity, and host lymphoreticular cells, particularly MP and neutrophils, congregated around the tumor cells. In IC-treated mice, only the polymorphonuclear WBC appeared to congregate around the tumor cells. IC had a dose-dependent cytotoxic effect on LAC cells. Doses of 10 and 25 µg had no significant effect on tumor growth, but 50-200 µg reduced the percentage of mice that developed tumors and 500 µg inhibited tumor development completely. In contrast, IC had no deleterious effect on the viability of EL4 cells, even at high concentrations. IC potentiated the growth and development of EL4 lymphomas in the mice while simultaneously killing MP. Thus, MP play an important role in regulating the growth of the EL4 lymphoma in C57BL10 mice. The nature of the cytotoxic effect of IC on the LAC cells is being studied. Selective killing of MP may abrogate an important growth-controlling mechanism within the tumor-bearing host. (45 refs)

- 78-6998 The Effects of Altered Phagocytic Activity on Growth of Primary and Metastatic Tumour** (Eng) Sadler, T. E. (Urology and Transplant Unit, Dept. Surgery, Royal Postgraduate Medical Sch., Hammersmith Hosp., London, W12 0HS, England); Jones, P. D. E.; Castro, J. E. *In: The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 155-163; 1977.

Silica (Si), cortisone acetate (CA), trypan blue (TB), diethyl stilbestrol (DES), and *Corynebacterium parvum* were used in macrophage phagocytosis studies that determined an inverse relationship between phagocytic index and metastatic behavior of tumors, but no apparent relationship between primary tumor growth (as measured by size) and phagocytosis. Si given iv (0.1 ml) and ip (0.5 ml) 3 hr later on days 4 and 9 after sc implantation of the Lewis lung carcinoma in the lower flank of C57BL/10 ScSn mice depressed the phagocytic index and significantly increased pulmonary metastases above control values. Similar results were obtained with CA (0.1 ml sc given on days 4 and 11 after tumor transplantation. DES (0.1 ml sc) given on days 0-4 after tumor inoculation and TB (0.4 ml ip 24 hr and 0.1 ml ip 3 hr prior to tumor implantation had little effect on the phagocytic index values, neither compound significantly altered the number of metastases. *C. parvum* (0.2 ml iv) given at tumor implantation caused a significant rise in the phagocytic index and a significant reduction in the number of metastases and overall tumor growth. Si

and DES also decreased tumor growth, but TB had no parent effect. (30 refs)

78-6999 Depression of Mononuclear Phagocyte Function in C57Bl Mice Bearing Lewis Lung Carcinoma. (Eng) Otu, A. A. (Dept. Surgery, St. Margaret's Hospital, Calabar, Nigeria); Russell, R. J.; Wilkinson, P. C.; Hevin, M-B. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 281-284; 1977.

To study the influence of Lewis lung carcinoma on macrophage function in C57Bl mice, the effects of growing tumors, tumor cell extracts, and sera from tumor-bearing animals on clearance of colloidal carbon from the circulation, chemotaxis of peritoneal macrophages in vitro, and the in vitro macrophage colony formation capacity of bone marrow derived cells were investigated. During the first 72 hr after tumor implantation, there was a pronounced depression in all these functions. For 2 wk thereafter, all functions were normal or above normal, but all were again severely depressed when the tumors metastasized and the mice had entered the terminal stage. Sera or tumor supernatant from tumor-bearing mice depressed carbon clearance in normal mice and inhibited the in vitro locomotion of peritoneal macrophages in normal mice. The data suggest that the tumor cells used a product which circulated in the blood and which was inhibitory to macrophages. (14 refs)

78-7000 Promotion of L1210 Tumour Growth by Macrophages. (Eng) Huget, R. P. (Dept. Microbiology, Lab. Immunology, Univ. Ulm, 7900 Ulm, W. Germany); Bitter-Suermann, D.; Opitz, H. G. *Z Immunitätsforsch* 154(5): 441; 1978.

To study the role of macrophages in tumor immunity, 10^4 L1210 mouse lymphoma cells derived from the peritoneal cavity or from in vitro cultures were injected sc into DBA/2 mice; and tumor development was monitored. Mice injected with peritoneal exudate cells developed tumors within 9 days. Tumor incidence was reduced and tumor development delayed by several days when in vitro derived cells were injected or when adherent cells were removed from the peritoneally derived cells prior to injection. Addition of adherent cells in high numbers to in vitro derived L1210 cells accelerated tumor growth, as did the addition of syngeneic liver cells. Differences in tumor development among the various groups were statistically significant ($p < 0.05$). The tumor-promoting effect of the adherent cells in the recipient was apparently not due to an increased proliferative capacity of the tumor cells. The data suggest that, under certain conditions, a cell population with the functional properties of macrophages is able to promote tumor development,

probably due to its nonspecific effect on the microenvironment of the growing tumor. (14 refs)

78-7001 Toxic Effects of Tumour Cells on Macrophages. (Eng) Fauve, R. M. (Unité d'Immunophysiologie cellulaire, Institut Pasteur, 25 rue du Dr. Roux, 75015 Paris, France); Hevin, M-B. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 264-270; 1977.

The substance(s) responsible for the toxic effects of Lewis tumor cells on peritoneal macrophages from C57Bl/6 and NCS mice was studied. Bradykinin in concentrations of 10^{-7} to 10^{-8} M increased the spreading of peritoneal exudate macrophages in vitro. In contrast, the spreading of macrophages was decreased in the presence of $0.1 \mu\text{g/ml}$ or more (up to $100 \mu\text{g/ml}$) of the active fraction obtained from Lewis tumor cell supernatant (AP). No decrease was observed when the macrophages were exposed to the same concentrations of the 10^3 - to 10^4 -mol wt fraction from fetal mouse kidney cells. Also, no decrease was observed when the peritoneal cells were incubated with bradykinin and then with AP. No increase in spreading was observed when the peritoneal cells were incubated first with AP and then with bradykinin. The data suggest that tumor culture supernatants inhibit the fixation of bradykinin to macrophage membranes. (27 refs)

78-7002 The Role of Complement Cleavage Products in Killing of Tumor Cells by Macrophages. (Eng) Schorlemmer, H. U. (Inst. Medical Microbiology, Johannes-Gutenberg-Univ., 6500 Mainz, W. Germany); Hadding, U.; Bitter-Suermann, D.; Allison, A. C. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 68-77; 1977.

Macrophages (MP) recovered from the peritoneal cavities of Swiss mice were cultured with pure guinea pig complement cleavage product C3b ($20 \mu\text{g/ml}$) or lipopolysaccharide (LPS: $25 \mu\text{g/ml}$), and the effect of these substances on the capacity of MP to lyse tumor cells was determined. ^{51}Cr -labeled L 5178 YE lymphoma cells were added to the MP 24 or 48 hr after culture initiation, and both cell types were cultured together for a further 16-18 hr. Unlike unstimulated control cultures, MP incubated with C3b or LPS lysed all or nearly all of the tumor cells. The MP also lysed P-815 mastocytoma cells and human lymphoblastic cells. The mastocytoma cells appeared to be the most sensitive to the lytic effect. This effect was C3b dose- and time-dependent, and it was considerably reduced in the presence of serum. The tachyphylaxis and cross-desensitization observed with reference samples of C3a identified the active agent in the media

of stimulated MP as C3a. Further evidence that the lytic activity is due to C3a comes from experiments using specific antiserum against C3a, which is presumably released from C3b-stimulated MP. These results show that C3b is a potent naturally occurring stimulator of MP activities, including tumor cell lysis. (11 refs)

- 78-7003 Tumor-induced Immunosuppression.** (Eng) Friedman, H. (Dept. Microbiology and Immunology, Albert Einstein Medical Center, Philadelphia, PA, 19141); Specter, S.; Watanabe, M.; Pan, S. H. *Am J Pathol* 93(2): 499-513; 1978.

Three tumor systems (lymphoma cell line FBL-3, mastocytoma cell line P815X, and plasmacytoma cell lines MOPC 104E, MOPC 31C, MOPC 173, and TEPC 15) were studied for their ability to modify humoral immunity to sheep RBC (SRBC) in vitro and in vivo. For the in vivo studies, BALB/c or DBA/2 mice infected with the Friend leukemia virus (FLV) complex or inoculated with tumor cells were challenged by ip or iv immunization with 4×10^6 SRBC. For the in vitro studies, 5×10^6 spleen cells from tumor-bearing or normal animals were cultured and immunized with 0.1 ml of a 0.1% suspension of SRBC (2×10^6 cells). FLV and all tumors depressed the hemolytic antibody plaque-forming cell response in susceptible mice, and spleen cells from normal animals were suppressed by intact tumor cells as well as by cell-free extracts from the plasmacytomas and mastocytomas. Cocultivation of FBL-3 lymphoma cells, which were initially induced by FLV in neonatal C57BL/6 mice, also resulted in immunosuppression. However, cell-free extracts from these immunosuppressive lymphomas were nonsuppressive. Thus, the lymphoma model did not support the concept that immunosuppression always occurs as a consequence of soluble factors. The mechanisms of suppression, although not fully defined, were different for each system investigated. (32 refs)

- 78-7004 Correlation Between Immunosuppression to Tumorigenesis. I. Humoral Immunosuppressing Factor.** (Eng) Hakim, A. A. (Dept. Surgery, Div. Surgical Oncology, Coll. Medicine, Univ. Illinois Medical Center, 180 Longwood Drive, Kankakee, IL, 60901). *Eur J Cancer* 14(11): 1249-1260; 1978.

The biological activities of agents released as a result of tumor cell proliferation were identified. Factors that alter cellular immunity and macrophage and lymphoid cell functions can be obtained from sera of animals bearing proliferating tumors. Inbred female Fischer rats and CFW mice bearing syngeneic mammary adenocarcinomas were used. The cytotoxicity of peritoneal macrophages and splenocytes against tumor cells and the effect of serum on the incorporation of ^3H -thymidine into normal splenocyte DNA in response to phytohemagglutinin (PHA) were assessed at various times during tumor growth. Serum enhanced the response of nor-

mal splenocytes to PHA if drawn before the 6th wk following sc injection of tumor cells; serum drawn after 7 wk suppressed this response. Macrophages and splenocytes from normal animals had no effect, those from animals bearing tumors enhanced tumor cell proliferation, and those from animals immunized against the tumor were cytotoxic against syngeneic tumor cells. Cell-free supernatants from mixed cultures of sensitized splenocytes, ie, splenocytes from immunized animals (at all ratios) and from animals bearing progressively growing tumors (at low ratios), with syngeneic tumor cells stimulated the response of normal syngeneic splenocytes to PHA. Since supernatants from cultures of splenocytes alone had no effect and supernatants from cultures of tumor cells alone had statistically significant suppressing activity, it is suggested that the suppressing agent(s) is released by the tumor cells. (58 refs)

- 78-7005 Adjuvant-induced Thymus-derived Suppressor Cells of Cell-mediated Tumour Immunity.** (Eng) Glaser, M. (Lab. Cell Biology, NCI, Bethesda, MD, 20014). *Nature* 275(5681): 654-656; 1978.

Inoculation of mice with complete Freund's adjuvant (CFA) markedly inhibited the ability of immune spleen cells to prevent simian virus 40 (SV40)-induced tumor growth in the Winn tumor cell neutralization assay and to lyse SV40-transformed cells in the ^{51}Cr -release assay. Female (BALB/c $\times$ C57BL/6)F₁ (CBF₁) mice were inoculated ip with 0.5 ml CFA and, immediately afterward, inoculated sc with 2×10^7 C57SV cells (an SV40-transformed cell line of BALB/c mice). T-cell-enriched fractions of spleen cells were purified and used in the ^{51}Cr -release assay against C57SV cells. A marked depression of cell-mediated cytotoxicity was observed. Challenge, sc, of another group of mice with 1×10^5 MKSA cells (an SV40-transformed line of BALB/c mice) 15 days after CFA immunization or mixing T-cell-enriched spleen cells from a third group of mice with 1×10^5 MKSA cells and injecting this mixture sc into normal CBF₁ mice resulted in death of most of these mice from progressive tumor growth. No tumors or death occurred in untreated control animals. Similarly, in the Winn assay, inhibition of tumor cell neutralization activity of lymphocytes from CFA-treated mice resulted in tumor growth and death of all animals as opposed to untreated mice, in which tumor cell neutralization resulted in complete protection against tumor growth. Thus, CBF₁ mice challenged with syngeneic SV40-transformed cells and CFA failed to develop effector cells; instead, they developed suppressor T cells that inhibited in vivo effector T-cell functions. Adult thymectomy reversed the suppression caused by CFA, which indicates that the intact adult thymus was necessary for the induction of suppressor cells. The results suggest that there is a delicate balance between the antitumor effects of adjuvants and their immunosuppressive effects. (17 refs)

- 78-7006 Enhancement of Avian Sarcoma Virus-induced Tumor Growth after Pretreatment with BCG.**

(Eng) Wainberg, M. A. (Lady Davis Inst. Medical Res., Jewish General Hosp., Montreal, Quebec, Canada); Israel, E. *Affect Immun* 22(2): 328-333; 1978.

The immunoprophylactic effects of BCG and the methanol extraction residue (MER) of BCG were investigated in chickens inoculated with avian sarcoma viruses (ASV). The chickens were inoculated in the wing web with 5 mg BCG or 0.5 mg MER 7 days before they were inoculated with 10^3 focus-forming units of virus. Of 17 chickens inoculated with BCG and ASV at the same site, 15 developed progressively growing neoplasms that eventually led to death. Injection of BCG into the wing web contralateral to that used for virus inoculation or injection of MER into the same wing web did not affect tumor development. Administration of BCG also gave rise to heightened levels of tumor-associated, cell-mediated immunity, both in chickens that received a subsequent injection of Prague strain A of Rous sarcoma virus and in normal, BCG-inoculated controls. BCG immunostimulation was apparently restricted to the cellular immune system, since an indirect immunofluorescence assay revealed no effect of BCG injection of the immunofluorescence staining capacity of virus-induced, tumor-bearing hosts. It is concluded that BCG prophylaxis is stimulatory to both Rous sarcoma development and to antitumor immunity in tumor-bearing hosts. (20 refs)

78-7007 **Characteristic Features of Immunologically-induced Changes in the Tumorigenesis in Mice of Various Strains.** (Rus) Volegov, A. I. (Lab. Pathophysiology, A. Hertsen Res. Oncological Inst., Moscow, USSR). *Biull Eksp Biol Med* 86(11): 572-574; 1978.

Tumor induction was compared in 3 to 4-mo-old C3HA, C3H/He, BALB/c, C57BL/6, and random-bred mice. Mice were immunized with BCG (0.01 or 1 mg in 0.2 ml of physiological saline) or with complete Freund adjuvant (CFA; 0.02 ml). Thirteen days after CFA administration and 30 days after BCG vaccination, animals were inoculated im with 20-methylcholanthrene (20-MC; 1 mg in 0.1 ml of vegetable oil). In C3H/He mice vaccinated with BCG, tumors started to develop significantly later than in non-treated mice; in C57BL/6 mice, BCG vaccination decreased the latent period of tumor development. CFA administration decreased the latent period of tumor development in C3H/He and C57BL/6 mice, inhibited tumor development in BALB/c and random-bred mice, and did not affect the tumor resistance of C3HA mice. These findings might indicate a role for hereditary factors in tumorigenesis. (12 refs)

78-7008 **Development of Immunocompetence in Hamsters and the Influence of DNA Oncogenic Viruses.** (Eng) Friedman, H. (Dept. Microbiology and Immunology, Albert Einstein Medical Center, Philadelphia, PA, 19141). *Fed Proc* 37(7): 2069-2071; 1978.

The effect of simian virus 40 (SV40) and adenovirus 12 (Ad12) infection on the development of immunocompetence in hamsters was investigated. Immunocompetence to sheep RBC developed rapidly in newborn hamsters. Animals inoculated on days 2-3 after birth developed few plaque-forming cells (PFC), but inoculation on days 5-7, 10-12, and 20-40 resulted in progressively greater responses (to $35-45 \times 10^3$ PFC/spleen). Inoculation of hamsters with SV40 at various times during the first 40 days of life had only a slight effect on PFC response 2-3 mo later. Hamsters given SV40 during the first week of life showed a slight depression in the antibody response to sheep RBC when challenged later in life. Tumors only occurred in animals treated with SV40 during the first 2 wk of life. Maturation of the immune response to sheep RBC was impaired in hamsters inoculated at birth with SV40. Injection of Ad12 into neonatal animals had similar effects. A slight to moderate effect on immune responsiveness to *Escherichia coli* lipopolysaccharide occurred after neonatal infection with SV40 or Ad12. Max effects were noted with animals 1-2 wk old. Cell-mediated immune responses to alloantigens, mycobacteria, and tumor virus-associated antigens were assessed in normal and virus-inoculated hamsters. Inoculation of normal hamsters with BCG as early as 2 wk of age resulted in marked cellular hypersensitivity: in vivo and in vitro reactions to challenge with purified protein derivative of tuberculin (PPD) were noted. Hamsters inoculated at birth with either SV40 or Ad12 also developed sensitivity to PPD after in vivo injection of BCG, but the in vitro response was weaker. The responsiveness of hamsters to 10% saline extracts of SV40 or Ad12 tumor extracts was directly related to prior inoculation at birth with virus. Sensitization became evident around 2 wk of age, reached a max around 3-4 wk, and decreased considerably by 60-100 days. This model may be useful in examining the interactions between host immune defense mechanisms and oncogenic DNA viruses that do not directly affect lymphoid cells. (25 refs)

78-7009 **Natural Killer Cells. In Vitro and In Vivo.** (Eng) Henney, C. S. (Fred Hutchinson Cancer Res. Center, 1124 Columbia St., Seattle, WA, 98104); Tracey, D.; Durdik, J. M.; Klimpel, G. *Am J Pathol* 93(2): 459-467; 1978.

Lymphoid cell populations from normal animals (rats, mice, and humans) can lyse tumor cells but not normal cells in in vitro ^{51}Cr release assays. The cells responsible for this cytotoxic activity have been characterized in the mouse and termed natural killer (NK) cells. In an attempt to discover whether NK cells are clonally distributed, they were absorbed onto monolayers of susceptible cells and then tested against other susceptible cells to see if the NK activity had been removed. The reactivity of NK cells from BCG-treated C57BL/6 mice against L5178 lymphoma cells was selectively removed by incubation of the effector cells on an L5178 cell monolayer but to a much lesser degree on a monolayer of normal DBA/2 spleen cells, which are insensitive to NK-mediated lysis. Adsorption on the L5178 cell monolayer also removed NK reactivity against susceptible human

Chang cells. On Chang cell monolayers, NK reactivity toward both L5178 and Chang cells was totally removed by adsorption. These experiments provided no evidence for clonal distribution of NK reactivities, but they indicated that target cell susceptibility to NK action may be determined by a shared antigenic specificity. Further BCG prophylaxis assays indicate that C57BL/6 NK cells were more efficient than growth-inhibitory adherent cells in vivo in retarding EL-4 ascites tumor growth. Although preliminary, these studies show that NK cells are an important host defense against progression to a neoplastic state. (25 refs)

78-7010 Modulation of Sensitivity to Natural Killer Cell Lysis after In Vitro Explantation of a Mouse Lymphoma. (Eng.) Becker, S. (Dept. Obstetrics and Gynecology, Sch. Medicine, Univ. North Carolina at Chapel Hill, Chapel Hill, NC, 27514); Kiessling, R.; Lee, N.; Klein, G. *J Natl Cancer Inst* 61(6): 1495-1498; 1978.

The kinetics of modulation to increased sensitivity to natural killer (NK) cell lysis was studied in explant cultures of a YAC ascites lymphoma induced in A/Sn mice by Moloney murine leukemia virus (M-MuLV). The sensitivity of all cultures to the same CBA spleen effector population was measured in a 6-hr ^{51}Cr -release assay. The lytic sensitivity was not significantly increased after 2 hr or 1 or 5 days of culture. The sensitivity was clearly increased by 3 wk, but max sensitivity was attained only after 1-2 mo of culturing. With the more sensitive competition assay, a change in sensitivity to NK lysis could be demonstrated as early as 2-24 hr of culture. Expression of the M-MuLV-determined, cell-surface antigen, measured by quantitative absorption with intact cells, increased in parallel with NK sensitivity, whereas the H-2a alloantigen concentration decreased during in vitro culture. These findings plus those from previous work indicate that establishment of an in vitro YAC line leads to profound membrane changes in the YAC cell. These changes may condition the cell to respond with an increased NK lytic susceptibility, even if the virally determined antigenic sites by themselves are not responsible for NK lysis. (19 refs)

78-7011 Alterations of the Antibody Response Following in Utero Exposure to Diethylstilbestrol. (Eng.) Luster, M. I. (Environmental Biology and Chemistry Branch, Natl. Inst. Environmental Health Sciences, Research Triangle Park, NC, 27709); Faith, R. E.; McLachlan, J. A. *Bull Environ Contam Toxicol* 20(4): 433-437; 1978.

The effects of a single administration of diethylstilbestrol (DES) to mice in the prenatal period on their immune response to sheep RBC (SRBC) and *Escherichia coli* 0127 lipopolysaccharide (LPS), thymic-dependent and thymic-independent antigens, respectively, were determined. Pregnant Swiss-Webster mice were injected with DES (1.0 mg sc) on day 16 of gestation. Offspring were immunized ip with either

0.2 ml of a 10% suspension of SRBC or 0.1 ml of a 0.1-mg/ml soln of *E. coli* 0127 LPS at age 7 wk. In utero exposure to DES did not alter the antibody response to SRBC. Lipid plaque-forming cells (PFC's) were decreased in DES-treated females and significantly increased in DES-treated males compared with controls. The enhanced action of DES on direct (IgM) LPS PFC in male mice could also be demonstrated during a secondary response (mice boosted with 0.01 mg LI 3 wk after the primary immunization), but antibody suppression was not observed in females. It is possible that exposure to DES during certain periods of fetal development stimulates or selectively programs a particular population of lymphocytes, particularly those involved with T-independent antigen responses, resulting in a relatively long-term alteration in the antibody response. (26 refs)

78-7012 Surface Membrane Changes of T Cells Induced by Syngeneic Tumour Cells. I. Formation and Uptake of Complexes of Ig and Tumour Antigens by T Cells. (Eng.) Dular, U. (Dept. Medicine, Immunology, Manitoba Inst. Cell Biology, Univ. Manitoba, Winnipeg, Manitoba R3E 0V9, Canada); Chow, D. A.; Paraskevas, F. *Int J Cancer* 22(5): 611-620; 1978.

The formation and uptake of complexes of immunoglobulin (Ig) and tumor antigens by spleen T cells were studied in mice inoculated ip with syngeneic tumor cells (L5178Y lymphoblastic leukemia and AKR thymoma). A dose of 10^7 cells from either source produced a significant increase in Ig-bearing spleen cells 6 hr later. Incubation of normal spleen cells in serum taken 6 hr after tumor cell inoculation reproduced in vitro the changes observed in the spleen cell population of the serum donors, demonstrating the presence of a cytophilic Ig that was taken up by T cells. Serum collected after tumor cell inoculation also contained Ig-antigen complexing factor (IACF) in the 4S fraction. Papain-digested tumor cell preparations, which contained specific tumor antigen activity, formed complexes with Ig in the presence of this factor. These complexes were cytophilic for a subpopulation of T cells, which thereby became Ig-positive. It is suggested that the cytophilic Ig present in the serum 6 hr after the injection of large numbers of tumor cells may also represent complexes of Ig and tumor antigens, the formation of which is mediated by IACF. (24 refs)

78-7013 Surface Membrane Changes of T Cells Induced by Syngeneic Tumour Cells. II. T-Cell Defects Induced by Small Tumour Cell Inocula or Tumour Cell Antigens. (Eng.) Chow, D. A. (Dept. Medicine and Immunology, Manitoba Inst. Cell Biology, Univ. Manitoba, Winnipeg, Manitoba R3E 0V9, Canada); Paraskevas, F.; Dular, U. *Int J Cancer* 22(5): 621-629; 1978.

T-cell defects induced by the injection of syngeneic L5178Y lymphoblastic leukemia cells in vivo were studied using

BA/2 mice. Injection of a large number of tumor cells was followed within 6 hr by the uptake of cytophilic immunoglobulin (probably complexes) by a subpopulation of T lymphocytes. This "6-hr T-cell response" was abrogated when small number of tumor cells (100) small amounts of an antigen-containing preparation from tumor cells, or repeated immunogenic doses of disaggregated human immunoglobulin are injected prior to the immunogenic challenge. Abrogation of the 6-hr T-cell response resulted in specific antitumor immunity, as measured by in vitro growth inhibition. It also resulted in loss of the enhancing effect of antibody formation against sheep RBC that is normally detected in a B-cell cooperative system when T cells are used 6 weeks after they have been primed with sheep RBC. It is suggested that this T-cell defect may represent a mechanism whereby tumor cells, in the early stages of their growth, interfere with the inductive stages of the immune response for a sufficient period of time to allow growth of the tumor beyond immune control. (25 refs)

78-7014 Resistance to Transplanted Cancer in Mice Increased by Live *Brucella* Vaccine. (Eng) Dard, L. (Centre Regional Anticancereux, Pontchaillou. F 35031, Rennes Cedex, France); Le Garrec, Y.; David, C.; Boujas, L. *Br J Cancer* 38(3): 464-467; 1978.

The effect of a chronic state of infection on the resistance of male (C57B16 x DBA2)F₁ mice to challenge by EL4 lymphoma cells was determined. Mice were vaccinated by iv injection of 5 x 10² or 5 x 10⁶ live *Brucella abortus*. One to 6 weeks later, half the animals in each group were killed; the remainder received 10³ EL4 lymphoma cells ip. Study of the lymphoid organs of the animals that were killed revealed that after injection of the lower dose, the number of bacteria increased until the third week. With the larger dose, however, the max number of bacteria was found as early as the first week. In all cases, the infection subsided by 6 wk. With the lower dose, the survival of lymphoma-bearing mice was slightly but significantly increased from weeks 3 to 5. Infection with the larger dose provoked a longer survival, particularly during weeks 1 and 2 after inoculation of the vaccine. Resistance to lymphoma was better correlated with the number of infectious organisms than with the degree of hyperplasia of the liver and spleen. It is suggested that *Brucella* may secrete a substance that inhibits cell division or that immune mechanisms against the bacteria may also act against the cancer cells. (23 refs.)

78-7015 Antigenic Content of an In Vitro Cellular Immunity Reactive Cell Surface Extract of Raji Cells. (Eng) Ng, M. H. (Medical Health Dept., Inst. Radiology Oncology, Queen Elizabeth Hosp., Kowloon, Hong Kong); Ng, W. S.; Ho, H. C. *Arch Environ Contam Toxicol* 8(3): 213-220; 1978.

The antigenic content of a Raji cell surface extract (TS) was studied by sequential absorption of rabbit antiserum to this extract with different cells. Anti-TS was reacted repeatedly with human blood cells followed by HeLa cells and human diploid fibroblasts. The residual reactivity was studied by stepwise absorption with an Epstein-Barr virus (EBV)-negative B lymphoblastoid cell line, BJAB, and then with B1-19, a clone derived from EBV-transformed BJAB cells. These processes delineated three kinds of reactivities in anti-TS having specificities for antigens on B blasts, EBV-determined cell surface antigen(s) and antigens that are exclusive to Raji cells. These results are compatible with the heterogeneous protein content of TS and with the results of earlier in vitro cell-mediated immunity studies using a similar preparation of Raji cell TS. (17 refs)

78-7016 High Lipid Fluidity of Leukemic Cell Membranes Through Host Immune Response and Shedding of Tumor Antigen-enriched Rigid Plasma Membrane Regions. (Eng) Van Blitterswijk, W. J. (Div. Cell Biology, Antoni van Leeuwenhoek-Huis, Netherlands Cancer Inst., Amsterdam, Netherlands); Van Der Sluis, P. J.; Hilgers, J.; Hilkmann, H. A.; Feltkamp, C. A.; Emmelot, P. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 341-344; 1978.

Thymus-derived leukemia (GRSL) in GR/A mice, maintained in ascites form by ip transplantation, possess mammary tumor virus (MTV)-induced cell-surface antigens (CSA). Seven days after transplantation, excess CSA are present in the ascites fluid in three forms: soluble, complexed, and on membrane vesicles. The microviscosity (fluidity) of phospholipids in intact cells and membrane fractions was determined by fluorescence polarization (P) using 1,6-diphenyl-1,3,5-hexatriene as a probe. Within a few transplantations in ascites form, the GRSL cells became fluid in normal nonirradiated hosts, but not in irradiated hosts. If cells from irradiated hosts were transplanted in nonirradiated hosts, the P value dropped, but the reverse did not occur to any marked degree. The increased fluidity of the cells in the ascites of normal hosts may reflect immunoselection and the shedding of CSA-enriched rigid vesicles: ie, abortive virus formation. The high fluidity of transplanted ascites GRSL cells may result in a decreased antibody-induced redistribution of antigens and a decreased sensitivity to immune killing. (7 refs)

78-7017 Modification of In Vitro Cell Mediated Immune Responses by Protein Components of a Leukemogenic Virus. (Eng) Fowler, A. K. (NCI, Frederick Cancer Res. Center, NIH, Frederick, MD, 21501); Twardzik, D. R.; Weislow, O. S.; Reed, C. D.; Hellman, A. In: *Advances*

in *Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977*. Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 234; 1978.

Freeze-thaw supernatants from banded Rauscher murine leukemia virus were chromatographed and the effluent fractions were tested for lymphocyte stimulatory activity and for inhibition of lymphocyte transformation induced by mitogens. Two samples from the first peak stimulated lymphocyte transformation but had no effect on mitogen-induced transformation. Material from the second peak exerted no stimulatory or inhibitory effect. A trypsin-sensitive component of the third peak suppressed mitogen-induced transformation and lipopolysaccharide stimulation. (no refs)

78-7018 Oncogenicity and Immunogenicity Associated with Membranes Isolated from Cell-free Ascites Fluid of Lymphoma-bearing Mice. (Eng) Raz, A. (Basic Res. Program, NCI, Frederick, MD, 21501); Barzilai, R.; Spira, G.; Inbar, M. *Cancer Res* 38(8): 2480-2485; 1978.

The immunogenicity and oncogenicity of membranes isolated from the cell-free ascites fluid of Moloney virus-induced lymphoma (YAC lymphoma)-bearing mice were determined. The supernatant obtained after the second centrifugation of the ascites fluid was separated into two fractions by ultracentrifugation: a supernatant containing soluble membrane fragments (AFM-s) and a pellet of insoluble membrane vesicles (AFM-p). Radioimmunoassay for murine leukemia virus p30 antigen (30,000-mol wt protein) indicated that the specific activity of this antigen is 20 times higher in the AFM-p fraction than in the YAC cell homogenate. Electron microscopy of the AFM-p fraction showed that viruslike (C-type) particles were associated with the plasma membrane vesicles. In vivo experiments with strain A mice indicated that the growth of an ascites tumor is associated with two biological activities, immunity and oncogenicity, and that both are present in the cell-free ascites fluid. The two activities can be disassociated by high-speed centrifugation or UV irradiation. In all cases, oncogenicity, but not immunogenicity, was abolished by UV irradiation. The immune activity is suggested to be associated with plasma membrane vesicles that contain a high specific activity of tumor-specific surface antigens. The oncogenic activity is associated with a tumor promoter factor that increases the efficiency of either intact lymphoma cells or the C-type particles. The tumor promoter factor is associated with the insoluble membrane fraction, since all oncogenic activity was associated with AFM-p. The immune activity is associated with both the soluble and insoluble fractions, since immunity was induced by both AFM-p and AFM-s. The possibility that shedding of plasma membrane vesicles and viruslike particles is associated with the same mechanism on the lymphoma cell surface membrane is explored. (38 refs)

78-7019 Surface Antigens in Acute Myeloblastic Leukemia: A Study Using Heterologous Antisera (Eng) Tupchong, L. (Nuffield Dept. Clinical Medicine, Radcliffe Infirmary, Oxford OX2 6HE, England); MacLennan, I. C. *Br J Cancer* 38(4): 481-495; 1978.

Attempts were made to confirm the presence of leukemia-specific antigens by producing rabbit antiserum against human leukemic myeloblasts by a variety of techniques. Ninety-five rabbits were immunized against myeloblasts from 19 acute myeloblastic leukemia patients by techniques designed to reduce the level of antibody against normal tissue antigens. Specificities of the antisera produced were determined by a K-cell-mediated cytotoxicity test and by a noncytotoxic radioimmune anti-immunoglobulin (¹²⁵I)-iodinated horse anti-rabbit binding assay. The antisera showed equal affinity to leukemic myeloblast preparations and normal splenic-lymphocyte preparations. When subsequently absorbed against pooled cadaveric human spleen cells to remove antibody against polymorphic antigens and tested against two leukemic myeloblastic preparations, 17/95 antisera had activity against at least one of the preparations. Several of the 17 absorbed sera also showed activity against phytohemagglutinin (PHA)-stimulated lymphoblasts. Although these antisera showed little activity against marrow per se, when they were absorbed twice against equal volumes of normal marrow, there was complete loss of activity against myeloblasts and PHA-stimulated lymphocytes, leading to the conclusion that specificity in these antisera was directed only against normal tissue antigens. It is concluded that although these sera contained activity against antigens common to leukemic myeloblasts and a minority population of normal marrow cells, they had no detectable activity against leukemia-specific antigens. 78-7020 Influence of Micrococcus, BCG and Related Polysaccharides on the Proliferation of the L1210 Leukaemia. (Eng) Verloes, R. (Laboratorium voor Chemie der Proteinen, Instituut voor Moleculaire Biologie, Paardenstraat 65; B-1640 Sint-Genesius-Rode, Belgium); Atassi, G.; Dumont, P.; Kanarek, L. *Br J Cancer* 38(5): 599-605; 1978.

The effects of *Micrococcus lysodeikticus* (ML), BCG, and series of structurally related complement-activating polysaccharides on the nonspecific and specific immune resistance of CDF₁ mice against L1210 lymphoid leukemia were compared. The mice were vaccinated ip with 10⁷ irradiated (8 kilorads) cultured leukemia cells and 1 mg BCG, ML, zymosan A, chitin, dextran sulfate, or irradiated cells alone 1 mo before ip challenge with 10⁶ leukemia cells. They had increased mean survival times (MST) of 165%, 67%, 159%, 98%, 76%, and 53%, respectively, over controls. These experiments were also conducted via the iv route, but the ip route was more effective in increasing MST over controls and inducing survivors to day 90 after tumor grafting. The addition of serial booster injections of 1 mg bacteria or polysac-

arides after tumor grafting increased the MST further and produced a higher percentage of long-term survivors. Treatments before or after tumor grafting with single or multiple doses of bacteria or polysaccharides alone was not able to increase MST over control values. Furthermore, serial injections of these complement activators + irradiated leukemia cells post-tumor grafting were also ineffective. (26 refs)

78-7021 Leukemia in AKR Mice. II. Two Modes of Suppression of In Vitro Antibody Formation by Leukemic Cells. (Eng) Roman, J. M. (Dept. Biological Sciences, Purdue Univ., Lafayette, IN, 47907); Golub, E. S. *Cell Immunol* 40(2): 316-325; 1978.

The in vitro suppression of the anti-sheep RBC (anti-SRBC) response of normal AKR mouse spleen cells by leukemic spleen and thymus cells from spontaneous AKR leukemias was further investigated. Leukemic cells that suppressed only syngeneic or semiallogeneic cells were termed restricted (R), and those that suppressed both syngeneic and allogeneic cells were called nonrestricted (NR). The suppression mediated by leukemic cells (representing approx 80% of spontaneous tumors) was overcome by the presence of irradiated allogeneic cells, allogeneic supernates, or mitogens. NR suppressors, however, exerted suppression in the presence of these substances. No differences in age, sex, or patterns of organ enlargement were observed between mice bearing R or NR tumors; in fact, individual leukemic AKR mice were sometimes found to have one lymphoid organ with R cells and another with NR cells. The combinations of allogeneic cells used for generating the supernates that overcame R suppression may differ from each other in background, histocompatibility antigen, or total genetic makeup. The activity of these supernates was nondialyzable and was partially sensitive to heat inactivation. When leukemic or normal cells were incubated with supernate and then washed, normal cells were still suppressible, but the leukemic cells were no longer suppressive, indicating that the supernates act on the leukemic cells rather than the normal cells. Suppression mediated by B10.A Haasch murine leukemia virus-induced leukemic cells was similar to that seen in AKR leukemic cells; both required cell contact, and 80% of the mice exhibited R suppression. This may indicate a mode of suppression common to many lymphoid leukemias, particularly those requiring congenital or long-term virus infection. The two types of suppression may reflect a modulation of leukemic cell-surface properties or a selection of leukemic cell populations resulting from specific host antitumor defense mechanisms. (22 refs)

78-7022 Leukemia in AKR Mice. III. Size Distribution of Suppressor T-Cells in AKR Leukemia and Neonatal Mice. (Eng) Mulder, A. M. (Dept. Biological Sciences, Purdue Univ., Lafayette, IN, 47907); Durdik, J. M.; Roth, P.; Golub, E. S. *Cell Immunol* 40(2): 326-335; 1978.

The size distribution of suppressor T cells of leukemic and normal AKR mice and neonatal (C57BL/6J x DBA/2J)F₁ (BDF₁) mice was compared by velocity sedimentation. All fractions of leukemic or neonatal thymus cells suppressed the immune responses of normal cells in vitro, but all fractions of normal AKR thymus cells enhanced these responses. Spleen cells showed a different pattern of suppression. Both neonatal and leukemic spleens contained suppressor cells, but these were found only among cells sedimenting at 3.3 mm/hr or faster; ie, large cells. Cells sedimenting slower than 3.3 mm/hr neither suppressed nor enhanced the response of normal cells. In contrast, small cells in the normal spleen contained cells that enhanced the responses of normal cells. Large and small suppressor thymus cells gave similar titration curves, indicating that suppression by the small cell fraction is not due to small numbers of large cells contaminating the population and that cells in both fractions have comparable specific activity. The suppression by lymph node cells was similar to that by spleen cells: only large cells suppressed. In contrast, an sc growing lymphoma exhibited a suppression pattern similar to that of the thymus. These data are consistent with the idea that the leukemia arising in the thymus exists as both large and small cells that are able to suppress normal responses but that only the large cells are exported to lymph nodes and spleen or that both large and small cells are exported but the small cells become large cells in the peripheral organs. Both neonatal and leukemic suppression was abrogated by x-irradiation or mitomycin C treatment. Both types of suppression required cell contact. The similarities between suppressor cells in neonatal and leukemic mice may indicate that the immunological events in spontaneous leukemia of AKR mice are to some extent a replay of the early events in normal T-cell differentiation. 78-7023 Protection of Newly-Hatched Chickens from Marek's Disease (JMV) by Normal Spleen Cells from Older Animals. (Eng) Lam, K. M. (Dept. Microbiology and Immunology, Temple Univ. Sch. Medicine, Philadelphia, PA, 19140); Linna, T. J. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers, J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 111-113; 1978.

The transfer of spleen cells from intact, nonimmunized adult chickens (≥ 8 wk old) that are naturally resistant to JMV to newly hatched chickens protected the recipients from JMV-induced leukemia. The results of various donor treatments (thymectomy, bursectomy, cyclophosphamide, or x-radiation, or their combinations) and spleen cell treatments (to remove macrophages or T cells) showed that non-T, non-B, nonmacrophage lymphoid cells are involved in the protection. 78-7024 Immunoprevention of Naturally Occurring Endogenous Murine Type-C RNA Viruses. (Eng)

Kende, M. (Lab. RNA Tumor Viruses, NCI, Frederick, MD, 21501); Stephenson, J. R.; Kelloff, G. J.; Al-Ghazzouli, I. K.; Dinowitz, M. *Nature* 273(5661): 383-385; 1978.

The induction of immunity to endogenous C-type viruses and the expression of these viruses were examined in BALB/c, NIH Swiss, and C57BL mice. Rauscher leukemia virus (R-MuLV) and Gross leukemia virus (G-MuLV) immunogens were injected sc on day 0 (200 µg), ip on days 14 and 28 (100 µg), and ip at 2-4 wk intervals (50 µg) for a total of 12 immunizations. All mice were killed 3 wk after the last immunization. All three strains had a virus-specific cytotoxic humoral immune response to both the R-MuLV and G-MuLV immunogens. Sera from C57BL mice were the most reactive, and sera from BALB/c were the least reactive. A predominant type-specific activity was seen with both immunogens, but a greater degree of cross-reactivity was seen with the former. At the time of killing, lymphocytes from all strains were nonreactive in cell-mediated cytotoxicity assays against the target cell used. Both immunogens induced an immunity to naturally occurring ecotropic virus in BALB/c mice: infectious ecotropic virus was detected in only 5/54 immunized animals in XC assays performed at the third passage vs 23/29 controls. At the first passage, only 3/54 animals yielded isolatable virus, and the mean titers were much less than those of controls. Both MuLV p30 and p12 expression in the spleen was closely correlated with the ability to isolate virus. Like BALB/c mice, immunized C57BL mice yielded few ecotropic virus isolates, but the incidence of isolates from control C57BL mice was lower than that from BALB/c mice. Investigations of class II and class III xenotropic virus activity at the third passage indicated that the immunized animals did not show marked reduction in endogenous xenotropic virus activity. However, the R-MuLV-immunized C57BL mice showed a trend of decreased activity in both infectivity and antigen assays that was significant with class II virus. (30 refs)

78-7025 Isolation of Leukaemia Specific Antigenic Macromolecular Moiety from Dinitrophenylated

Normal Human Leukocytes. (Eng) Karande, A. A. (Cancer Res. Inst., Tata Memorial Centre, Bombay 400 012, India); Sahasrabudhe, M. B. *Indian Acad Sci Proc [B]* 87(1): 1-8; 1978.

In an attempt to isolate tumor-specific antigen from non-malignant tissues, conformational changes were introduced in the cell-surface macromolecules of normal human WBC, and changes in the antigenicity of the cells were studied. Normal WBC suspensions were dinitrophenylated by treating them with 1-fluoro-2,4-dinitrobenzene (10⁴ molecules/cell). Agglutination titers of 256 to 2,048 against leukemic cells were obtained with rabbit antiserum against the dinitrophenylated normal WBC. Affinity chromatography on an antibody-sepharose column yielded three fractions, two of

which contained leukemia-specific antigenic moieties. Strong specific antileukemic agglutinating activity was obtained when the latter two fractions were injected in an oil-in-water emulsion into mice. The antileukemic agglutinating activity was weak when the pooled fractions were given in saline. The antigenic fractions had mol wts of 48,000 and 21,000, respectively. The use of the oil-in-water emulsion provided the necessary core for the antigenic proteins to orient themselves and perhaps acquire the same hydrophobic and hydrophilic orientation as that seen on intact cell membranes. (27 refs)

78-7026 Cell Sorter Analysis of Leukaemia-associated Antigens on Human Myeloid Precursors. (Eng)

Janossy, G. (Dept. Immunology, Royal Free Hosp., Pond St. London NW3, England); Francis, G. E.; Capellaro, D.; Goldstone, A. H.; Greaves, M. F. *Nature* 276(5684): 176-178; 1978.

The presence of leukemia-associated antigens on human bone marrow cells was studied by separating them in a fluorescence-activated cell sorter (FACS) according to their binding of anti-Ia-like or anti-acute lymphoblastic leukemia (ALL) antibodies. After most mature granulocytic and erythroid cells were eliminated, adult marrow samples contained 10%-14% cells reactive with anti-Ia serum (Ia⁺ cells). These Ia⁺ cells included larger cells, mainly myeloblasts and promyelocytes, and smaller SmIg⁺ (surface membrane immunoglobulin-positive) B lymphocytes. The Ia⁻ cells were myelocytes, maturing granulocytic and erythroid cells, a few lymphocytes, and <5% myeloblasts and promyelocytes. Colony and cluster-forming cells were present in both Ia⁺ and Ia⁻ fractions. Clone-forming cells were found almost exclusively among the intermediate-to-large cells, suggesting that small Ia⁺, ALL⁺ non-T, non-B cells did not form myeloid colonies. This was confirmed by staining fetal marrow cells with anti-ALL serum, separating them on the FACS, and culturing them for 7 days. The ALL⁺ and ALL⁻ fractions gave, respectively, 3.2 and 626 clones per 10⁴ cells. These results suggest that a proportion of human myeloid precursors are Ia⁺ and that a few are very strongly Ia⁺. The results also suggest that the two Ia⁺ non-T, non-B cell types (the smaller ALL⁺ cell and the larger ALL⁻ cell) might represent the target cells for leukemia transformation in the common (non-T, non-B) form of ALL and in acute myeloblastic leukemia, respectively. (27 refs)

78-7027 Cell-mediated Anti-tumor Response in the RL(male) 1 System. I. T Nature, Nature, H-2

DInvolvement and Antigenic Specificity of the Effector Cells. (Eng) Duprez, V. (Laboratoire d'Immunologie et de Virologie des Tumeurs, INSERM U 151, Hôpital Cochin, 27, Rue du Faubourg Saint Jacques, F-75674 Paris Cedex 14, France); Gomard, E.; Levy, J. P. *Eur J Immunol* 8(9): 650-655; 1978.

the effector cells involved in the cell-mediated antitumor response in the RL male 1 lymphoma cell system were characterized. After in vivo priming and in vitro secondary stimulation by radio-induced RL(male) 1 cells (RLC), syngeneic BALB/c splenic lymphocytes showed a specific but very weak cytolytic activity against target RLC. Under the same experimental conditions, spleen cells from (B6 x BALB/c)F₁ were at least 100-fold more efficient. In both cases the effector cells were cytolytic T lymphocytes (CTL), and normal M2 antigens of the tumor cell surface were involved in the effector-to-target cell interaction. The immune CTL were highly specific for target RLC; of cells from 13 other transplantable lymphomas as well as leukemic cells from spontaneously leukemic AKR mice, only P815 mastocytoma cells showed weak cross-reactivity. The exact nature of the antigen recognized by anti-RLC CTL remains unknown; the hematopoietic histocompatibility antigens which could have accounted for the F₁ antiparent reaction appear irrelevant. (28 refs)

78-7028 Increased Incidence of Spontaneous Lymphomas in Thymectomized Mice. (Eng) Cornelius, E. A. (Section Nuclear Medicine, Dept. Diagnostic Radiology, Yale Univ. Sch. Medicine, New Haven, CT). In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 1975-351; 1977.

The influence of thymectomy on the incidence of spontaneous lymphomas was examined in (C57BL/1 x A)F₁ [(BA)F₁] mice and in (SJL/J x C57BL/1)F₁ [(SB)F₁] mice. Mice were thymectomized (Tx) within 24 hr of birth. Tx(BA)F₁ mice demonstrated impaired cellular immunity, histologic changes similar to the graft-vs-host reaction, and a markedly increased incidence of lymphomas compared with normal control mice of the same age. This difference was greatest before old age, at which time tumors became more frequent in controls. Presumptive evidence of a subcellular oncogenic agent in the tumors of Tx mice was obtained. Most tumors arising in Tx(BA)F₁ mice were rejected on transplantation into normal syngeneic controls, suggesting that the impaired cellular immunity of the Tx mice permitted the growth of tumors that were more strongly antigenic than those that occurred in normal mice. The incidence of nonlymphoid tumors was not increased in Tx(BA)F₁ mice. In (SB)F₁ mice, thymectomy was associated with a moderately increased incidence of lymphomas for a 4-mo period. Tx(SB)F₁ mice, unlike Tx(BA)F₁ mice, demonstrated no lymphoproliferative changes and no graft-vs-host like lesions. (11 refs)

78-7029 T-Cell Lymphoma Induction by Radiation Leukemia Virus in Athymic Nude Mice. (Eng) Ricciardi-Castagnoli, P. (Cancer Biology Res. Lab., Dept. Radiology, Stanford Univ. Medical Center, Stanford, CA, 94305); Lieberman, M.; Finn, O.; Kaplan, H. S. *J Exp Med* 148(5): 1292-1310; 1978.

Extrathymic lymphoblastic leukemias developed in 3/5 athymic nude BALB/c mice and 1/8 athymic nude NIH Swiss mice inoculated with radiation-induced leukemia virus (RadLV), and a permanent cell line (BALB/Nu₁) was established from a BALB/c lymphoma. BALB/Nu₁ was highly tumorigenic when injected ip into BALB/c and NIH/Swiss nude mice, and electron microscopy of tumor cells showed features of a typical stimulated lymphocyte and numerous C-type viral particles, designated RadLV/Nu₁ virus. Reverse transcriptase activity of this virus coincided with that of ³H-labeled material in the 1.15-1.1 g/cm³ gradient density region. On polyacrylamide gel electrophoresis, RadLV/Nu₁ and RadLV/VL₃ viruses coelectrophoresed in most protein regions except the major envelope protein (gp71). Radioimmunoassay indicated that RadLV/Nu₁ possessed surface antigens common to or cross-reacting with the envelope antigens of RadLV/VL₃ and, to a lesser extent, xenotropic and ecotropic murine leukemia viruses. Cross-reactivity between the gp71 determinants of RadLV/Nu₁ and RadLV/VL₃ was demonstrated by membrane immunofluorescence test. RadLV/Nu₁ had thymotropic and leukemogenic activity in C57BL/Ka mice, but not in NIH/Swiss nude (nu/nu) or (nu/+). In vitro RadLV/Nu₁ was B-tropic, poorly fibrotropic, and limited to xenotropic activity. In several areas, therefore, RadLV/Nu₁ appeared to be closely similar to its parent virus RadLV. Terminal deoxynucleotidyl transferase activity in the lymphoma cells of BALB/c nude and NIH/Swiss nude mice was tenfold higher than in normal spleen cells of control nude mice. When tested for several T-cell antigens, these lymphoma cells were seen to be Thy-1.2+, Ly-2.2+, Ly-1.2-, and TL-. Immunoglobulin determinants were not noted. This profile resembles that of mature peripheral T cells, although the antigens were present in much lower quantities. (32 refs)

78-7030 Atypical Lymphoid Leukemia in Ataxia Telangiectasia. (Eng) Levitt, R. (Section Publications, Mayo Clinic, 200 First St. SW, Rochester, MN, 55901); Pierre, R. V.; White, W. L.; Siekert, R. G. *Blood* 52(5): 1003-1011; 1978.

The case reports of two sisters (23- and 25-yr-old) with ataxia telangiectasia (AT) are presented. The elder sister developed an atypical subacute lymphocytic leukemia characterized by large atypical lymphocytes and prolymphocytes, and the absence of organomegaly. Results of cytogenetic banding disclosed that both patients had identical abnormalities associated with chromosome 14 (t(14q11:14q34)) with the leukemic sister showing additional stable aberrations. The presence of the marker in the leukemic cells of the elder sister supports the theory that her leukemic cells arose from a preexisting AT lymphocyte clone. Furthermore, it is suggested that the

presence of an abnormal lymphocyte clone, depressed cellular immunity, or susceptibility to chromosomal damage or rearrangement may be responsible for the increased incidence of malignancy in AT patients and AT carriers. (37 refs)

- 78-7031 Crossed Tumor Antigenicity Between the Experimental Tumors Ca M, Ca H, Ca O and Ca M₄.** (Spa) Cuadrado, S. P. (Departamento de Immunopatologia, Instituto Nacional de Oncologia, Madrid-3, Spain); Moreno Koch, M. C.; Tome Paule, C. *Rev Esp Oncol* 25(1): 45-47; 1978.

The cross antigenicity between the experimental tumors Ca M, Ca H, Ca O and Ca M₄ was studied in C₃H/he mice. Eighty animals first received a Ca M tumor transplant. After the surgical removal of this tumor, four subgroups of animals received transplants of Ca M (autograft), Ca H, Ca O or Ca M₄ tumors. Another group received a primary Ca H transplant; its two subgroups received secondary Ca H and Ca M grafts. The third group received primary Ca O transplants; the secondary transplants were Ca M and Ca O in the subgroups. The fourth group was grafted first with Ca M₄, and then Ca M and Ca M₄ were grafted in the subgroups. The immune status produced by the primary Ca M and Ca M₄ tumors offered protection against subsequent transplants of both Ca M and Ca M₄ (crossed antigenicity), but not against Ca O and Ca H transplants. The immunity produced by Ca O offered, however, protection against a subsequent Ca M transplant. The Ca H tumor failed to produce any immune protection against other tumors. The absence of crossed antigenicity between tumors in which viral particles are present suggests that these viral particles are not involved in the pathogenesis of the tumors. (no refs)

- 78-7032 HLA and Glioma.** (Eng) de Moerloose, P. (Transplantation Immunology Unit, Div. Immunology and Allergy, Hopital Cantonal, 1211 Geneva 4, Switzerland); Jeannet, M.; Martin-Achard, A.; de Tribolet, N.; Seiler, R.; Guanella, N. *Tissue Antigens Histocompat Immunogenet* 12(2): 146-148; 1978.

Eighty glioma patients were typed for several histocompatibility antigens (HLA-A, -B, and -DRw), with age at time of diagnosis, sex, blood, group, and degree of malignancy being considered. Phenotypic frequencies of Bw35 and Drw1 antigens were increased in patients compared with controls, but when p values were corrected by the number of antigens tested (35), the results were not significant. (7 refs)

- 78-7033 Immunotherapy of Chemically-induced Tumors in the Hamster Cheek Pouch with Dinitrochlorobenzene.** (Eng) Marshack, M. (Dept. Oral Pathology, Loyola Univ. Sch. Dentistry, Maywood, IL, 60153); Toto, P.; Kerman, R. *J Dent Res* 57(4): 625-630; 1978.

The effect of dinitrochlorobenzene (DNCB) sensitization in the buccal pouch of hamsters prior to or after the induction of cheek pouch tumors with 7,12-dimethylbenz(a)anthracene (DMBA) was studied. For tumor induction, the buccal pouches were painted with 0.5% DMBA in mineral oil 2x/wk for 14 wk. For DNCB sensitization, two pellets of cotton, each containing 1 ml of 0.1% DNCB soln, were inserted in each pouch and left to remain until expelled by the hamster (usually after 10 min). Hamsters were given two DNCB treatments, 48 hr apart; 14 days later, the pouches were challenged with a 0.01% DNCB soln. Hamster cheek pouches treated with DMBA only developed advanced invasive squamous cell carcinomas. Infiltration of the connective tissue surrounding the tumors was slight, with an av of 1 lymphocytes and < 1 plasma cell/50 μ m². When hamsters were treated with DMBA and then DNCB, benign noninvasive papillary tumors resulted. Hamsters pretreated with DNCB followed by DMBA (starting at the same time as the challenge dose of DNCB was being responded to) developed squamous cell carcinoma in situ. However, with repeated (1-4) DNCB rechallenges, 5/16 pouches developed noninvasive papillary tumors characterized by hyperplasia with dyskeratosis and 11 pouches showed no tumors. A lymphocytic and plasma cell-mediated response was seen in all DNCB-treated groups, and the lymphocyte response was greatest (av of 50 lymphocytes/50 μ m²) in hamsters treated with DNCB following tumor induction. Lymphocytes not only invaded the lamina propria but also the epithelium. These lymphocytes may be reacting to tumor-associated antigens. (11 refs)

- 78-7034 Antibody to Epstein-Barr Virus in Patients with Carcinoma of the Nasopharynx.** (Eng) Inuyama, Y. (Dept. Oto-rhino-laryngology, Sch. Medicine, Keio Univ. Tokyo, Japan); Asaoka, K.; Nakajima, Y.; Horiuchi, M.; Takasaki, K.; Ozu, R. *Keio J Med* 26(2): 79-89; 1977.

Antibody titers against the viral capsid antigen (VCA) of Epstein-Barr virus (EBV) were studied in 59 patients with a malignant tumor of the nasopharynx (51 carcinomas, 8 lymphomas), 117 patients with a tumor of other sites of the head and neck, and 263 patients without malignant disease (controls). The geometric mean titer was 1:794 and the antibody-positive rate 82% in the patients with nasopharyngeal tumors. The corresponding values were 1:190 and 37% in patients with other head and neck tumors and 1:120 and 20% in the controls. Riddit analysis indicated that the differences among the groups were statistically significant. The anti-VCA titer was determined repeatedly in patients with nasopharyngeal carcinoma. It was found that in cases of recurrence or metastasis, the titer was elevated markedly, but in patients with a short- or long-term remission, it was decreased. However, radiotherapy appeared to increase the anti-VCA titer. This could result from either antigen stimulation due to the destruction of cancer cells or the production of more antibodies by B cells following relief from the suppression of T cells. Anti-VCA titers might be useful in the

gnosis of nasopharyngeal carcinoma. The findings suggest that EBV is either carcinogenic or is a passenger virus in nasopharyngeal carcinoma. (16 refs)

78-7035 Protective Effect of Thymectomy in a High Cancer Risk Population. (Eng) Papatestas, A. (Dept. Surgery, Mount Sinai Sch. Medicine, New York, NY 10029); Kark, A. E.; Jenkins, G.; Aufses, A. H. *In: Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 6-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 353-365; 1977.

The cancer risk in myasthenia gravis (MG) was investigated in relation to thymic pathology, the differences in cancer incidence between patients with and without thymectomy (Tx), and the role of Tx in altering the risk of oncogenesis. The records of 2,000 patients registered at a New York hospital and a London hospital were reviewed; 189 of these patients had undergone Tx. A total of 149 neoplasms were found in the entire population. In women, a significant increase in relative risk (RR) was present prior to Tx both in those with thymomatous MG and those with associated thymomas. Following Tx, the relative risk decreased and there was no difference from the expected numbers. In men, the RR prior to Tx was also higher than that following Tx, but there were no significant differences in RR. In both sexes, patients with thymomas and those with many germinal centers had a higher RR than patients without thymomas. The post-Tx decrease in RR was more marked in patients who were operated early after the onset of disease and in those who had reached remission. The observed numbers of neoplasms in the period after the onset of remission were lower than expected, but in all other periods observed numbers were higher than expected. Thus, Tx may have a protective effect against the high cancer risk associated with thymic abnormalities. (25 refs)

78-7036 Immunological Studies in Epidermodysplasia Verruciformis. (Eng) Jablonska, S. (Dept. Dermatology, Warsaw Sch. Medicine, ul. Koszykowa 82a, 02-008 Warsaw, Poland); Orth, G.; Jarzabek-Chorzelska, M.; Rzesza, G.; Obalek, S.; Glinski, W.; Favre, M.; Croissant, O. *Bull Cancer (Paris)* 65(2): 183-190; 1978.

Immunofluorescence (IF) and cell-mediated immunity (CMI) studies were made of 14 cases of Epidermodysplasia verruciformis (EV), 10 familial and 4 nonfamilial. Numerous malignancies plus one occurrence of Bowen's disease were found in three nonfamilial cases; malignancies were also found in three nonfamilial cases. Attempts were made to determine (1) the antigenic differences of viruses inducing EV by IF; (2) the significance of CMI for progression of the disease and possible malignant transformation; (3) whether

the types of human papillomavirus (HPV) inducing EV differ in their oncogenic potential; and (4) any possible correlation of the type of HPV with CMI. Two different types of HPV, HPV-3 and HPV-4, were found in the EV cases. There was a relationship between the type of HPV and the clinical picture of EV as well as the occurrence of malignant transformation. HPV-4 was more oncogenic: of the 12 cases typed, transformation occurred in 1/7 with HPV-3 and in 5/5 with HPV-4. CMI was depressed in most of the active cases and preserved in regressing and abortive cases. However, a low CMI was found in EV cases infected with HPV-3 and in persistent flat warts, also due to HPV-3, that did not undergo malignant transformation. In contrast, in a case of EV due to HPV-4, malignant transformation occurred in spite of a preserved, although lowered, CMI. HPV-1, which is responsible for plantar warts, and HPV-2, responsible for common warts, have no evident oncogenic potential. (29 refs)

78-7037 Common Human Melanoma Membrane Antigens Detected by Mixed Hemadsorption Microassay with Serum from a Patient Undergoing Immunotherapy with Autologous Tumor Cells. (Eng) Liao, S. K. (Ontario Cancer Foundation Hamilton Clinic, c/o Henderson General Hosp., 711 Concession St., Hamilton, Ontario, L8V 1C3, Canada); Leong, S. P.; Sutherland, C. M.; Dent, P. B.; Kwong, P. C.; Krementz, E. T. *Cancer Res* 38(12): 4395-4400; 1978.

The postimmune serum (PIS) and preimmune plasma of a patient with malignant melanoma who received 28 immunizations with autologous, irradiated, cultured melanoma cells plus BCG were tested for their reactivity in mixed hemadsorption microassays against several cell lines. No reactivity against any of the five allogeneic melanoma cell lines or five nonmelanoma lines tested was detected in the preimmune plasma, but strong reactivity against all five melanoma lines in varying titers (1:2,560 to 1:40,960) and against 2/5 nonmelanoma lines in lower titers (1:320 and 1:1,280) were found in the unabsorbed PIS. Absorption with human AB RBC, pooled peripheral blood WBC, and spleen homogenates of normal adults, did not alter this reactivity. Further absorption with cells of a human laryngeal carcinoma (KB) line reduced reactivity against the five melanoma lines 4- to 16-fold (1:160 to 1:5,120), but a strong residual common reactivity against these lines still remained. This absorbed serum no longer reacted with any of the five nonmelanoma lines. Removal of reactivity against fetal calf serum (FCS) by absorption with insolubilized FCS reduced reactivity against the melanoma cell lines to the same extent, but failed to remove reactivity against the nonmelanoma cell lines completely. Further absorption of PIS with human fetal homogenate or BCG had no effect on its reactivity against the melanoma lines. Blood group isoantigens, histocompatibility locus antigens, and FCS were ruled out as causes of the observed seropositivity against the melanoma cell lines in the final two stages of sequential absorptions. These data provide further evidence for the existence of common melanoma-associated antigens. (32 refs)

- 78-7038 Genetic Control of Resistance to Tumors.** (Eng) Phillips-Quagliata, J. M. (Dept. Pathology, New York Univ. Medical Center, 550 First Ave., New York, NY, 10016); Walker, M. C. *Am J Pathol* 93(2): 487-498; 1978.

To determine whether genes mapping within the major murine histocompatibility complex (H-2) control resistance to a BALB/c plasmacytoma (MPC-11), hybrid mice from over 20 parental strains were injected sc in the right dorsal flank with 3×10^5 viable MPC-11 cells (a dose fatal to 100% of BALB/c controls). F₁ hybrids between BALB/c and other BALB congenic resistant (CR) strains were as susceptible to MPC-11 as homozygous BALB/c mice, which demonstrated that H-2 heterozygosity was not sufficient for resistance. F₁ hybrids between BALB/c and all but two recombinant inbred strains were resistant. In (BALB/c x B10 CR)F₁ hybrids, resistance was dependent on the presence of a single dominant autosomal gene or gene complex that segregates independently of H-2 and that has slight differential effects on various H-2 haplotypes. The resistant mice became susceptible to MPC-11 cells injected after 450 rads γ irradiation, but they remained resistant after iv silica injection. Studies of hybrids between B6 and BALB/c mice suggested that their tumor resistance was decreased by the expression of Gross viral antigens of some other viral determinant. The mechanism for this is not understood, but it might involve tolerance, suppression, or enhancing antibody. (39 refs)

- 78-7039 Resonance Raman-Spectroscopic Studies of the Hapten Features Involved in the Binding of 2,4-Dinitrophenyl Haptens by the Mouse Myeloma Proteins MOPC 315 and MOPC 460.** (Eng) Kumar, K. (Dept. Chemistry, St. Mary's Univ., Halifax, N.S., Canada); Phelps, D. J.; Carey, P. R.; Young, N. M. *Biochem J* 175(2): 727-735; 1978.

The resonance Raman spectra of four dinitrophenyl (Dnp) haptens were characterized, and the binding of the haptens to mouse myeloma proteins MOPC 315 IgA and MOPC 460 IgA was studied by resonance Raman spectroscopy. The interactions between a given hapten and MOPC 315 IgA were often quite distinct from those between the same hapten and MOPC 460 IgA. More importantly, the nature of the R side chain in a Dnp-NHR compound appeared to modify the contacts between the chromophore and the protein. Thus, with the haptens studied, there was no unique set of contacts between the Dnp group and the binding site. The contacts expected between ϵ -2,4-dinitrophenyl-L-lysine and the site on MOPC 315 IgA were not detected. However, the contacts between this hapten and the site on MOPC 460 IgA were close to those predicted by a model for MOPC 315 IgA. (25 refs)

- 78-7040 Symmetry of Binding Sites of a Mouse IgA Myeloma Protein (MOPC 315).** (Eng) Eisen-

berg, R. (Dept. Medicine, Univ. North Carolina, Chapel Hill, NC, 29514); Plotz, P. *Biochemistry* 17(22): 4801-4807; 1978.

The mechanism of monovalency of the 7S subunit of a mouse IgA myeloma protein (MOPC 315) against a large antigen was investigated using affinity labels. In an equilibrium Farr assay, the subunit was shown to have only one valence for a univalent 40,000-mol wt antigen (dinitrophenyl-dextran). In four experiments, an average valence of 1.1 and a K_a of 1.4×10^6 were obtained. This monovalency did not appear to be an artifact of the Farr assay used, as a small hapten (dinitrophenyl- ϵ -aminocaproic acid) tested in the same assay gave an average valence of 1.8 and a K_a of 1.4×10^6 . Blocking binding sites with a small affinity labeling hapten, bromoacetyl-dinitrophenyl-lysine, quantitatively reduced the binding of large molecules in a manner strongly favoring the model of a symmetric 7S molecule, in which the binding of a large ligand to one site inhibits an adjacent site from binding a second large ligand. The results of dinitrophenyl-lysine-agarose column chromatography strongly favored the steric hindrance model of MOPC 315 monovalency. Such a model implies that the Fab binding sites are symmetrically arranged in the 7S subunit, but that they are too close together to permit two large antigens to bind simultaneously. (32 refs)

- 78-7041 Autoimmunity and Tumor Resistance. 3-Methylcholanthrene Tumorigenesis in New Zealand Black Mice.** (Eng) Morton, J. I. (Div. Immunology, Dept. Medicine, Univ. Oregon Health Sciences Center, Portland, OR, 97201); Siegel, B. V.; Moore, R. D. *Am J Pathol* 93(2): 469-485; 1978.

The susceptibility of New Zealand Black (NZB) mice to epidermal tumors induced by 3-methylcholanthrene (3-MCA) was examined as a function of age, sex, immune and autoimmune status, immunosuppressive treatment, and hepatic aryl hydrocarbon hydroxylase (AHH) levels. Results of a comparison of the frequency, type, and distribution by sex of 3-MCA-induced tumors in NZB, BALB/c, C57BL/6, and SJL/J mice given a single sc injection of 150 μ g 3-MCA at age 4 mo revealed that NZB mice had a longer tumor latency period and a lower tumor incidence than the other strains. Although most of the tumors in the other groups were sarcomas, the NZB group had an almost equal number of sarcomas (21) and squamous cell carcinomas (18). In NZB mice injected with 3-MC at different ages, 4-mo-old females responded with the greatest incidence and most rapid development of tumors. Treatment with antithymocyte serum decreased the final incidence of tumors while x-irradiation with 500 rads accelerated the onset of tumors in 4-mo-old NZB mice. The development of glomerulonephritis and hematopoietic carcinomas was independent of 3-MCA injection and the presence of skin tumors. Liver AHH specific activity following ip injection of 100 mg/kg 3-MCA was highest in female NZB mice, and the activity increased gradually with age. (30 refs)

78-7042 Circulating Immune Complexes in Rats Bearing Chemically Induced Tumors. I. Sequential Determination During Growth of Tumours at Various Body Sites. (Eng) Hoffken, K. (Cancer Res. Campaign Lab., Univ. Nottingham, Univ. Park, Nottingham NG7 2RD, England); Hoffken, M. R.; McLaughlin, P. J.; Moore, V. E.; Baldwin, R. *Int J Cancer* 21(4): 496-504; 1978.

transplanted 3-methylcholanthrene-induced sarcoma (Mc7) and a 4-dimethylaminoazobenzene-induced hepatoma (D23) were used to determine whether the binding of circulating immune complexes to the complement component C3 can be employed to monitor tumor growth in rats. Circulating immune complexes were measured in sequential monitoring studies in tumor-bearing WAB/Not rats. The assay employed was based on the radioimmunoprecipitation of immune factors with ^{125}I -Clq or on an indirect test whereby the inhibition of binding of ^{125}I -Clq to IgG aggregates by tumor-bearer sera were measured. After an initial peak coincident with a tumor diameter of about 0.5 cm, the Clq-binding activity of sarcoma-bearer sera decreased until they ultimately bound less Clq than normal rat serum. Sc implantation or growth of D23 hepatoma resulted in a change in Clq binding by tumor-bearer serum similar to that observed with sc inoculation of Mc7 sarcoma. The percentage of specific inhibition of tumor-bearer serum decreased at late stages of tumor growth, but it was reversed in rats whose tumors were excised 7 days after implantation. Antibody reactivity increased with increasing tumor burden, and the specific humoral activity was lost following resection. Following iv tumor cell injection, immune-complex levels increased until the terminal stages of the disease. Measurement of Clq-binding serum factors represents a useful method for monitoring the growth and burden of experimental animal tumors. (33 refs)

78-7043 Induction of a Tumor with Greatly Increased Metastatic Growth Potential by Injection of Cells from a Low-Metastatic H-2 Heterozygous Tumor Cell Line into an H-2 Incompatible Parental Strain. (Eng) Kerst, R. S. (Natl. Cancer Inst. Canada Res. Group, Dept. Pathology, Queen's Univ., Kingston, Ontario K7L 3N6, Canada); Twiddy, R. R.; Robertson, D. M. *Int J Cancer* 22(5): 533-594; 1978.

In H-2-heterozygous sarcoma, MDAY, originally induced by 3-methylcholanthrene in an (A x DBA/2) F_1 (H-2a x H-2d; DBA/2 F_1) hybrid was adapted for growth in the H-2-incompatible DBA/2 parent strain by serial ip transplantation of ascites tumor cells. Upon serial passage, the cells gradually lost their K-2Kk antigenicity. When these H-2Kk-negative, H-2d-positive variant (MDAY-D2) cells were injected sc into DBA/2 AD F_1 recipients, they gave rise to highly metastatic tumors. Widespread metastases to liver, spleen, lungs, and kidneys were evident within 12-18 days. There was total replacement of liver and spleen within 2-3 wk. The tendency to metastasize and loss of the K-2Kk haplotype appeared stable and irreversible. In contrast, MDAY cells either did not

metastasize or did so only to the liver in AD F_1 mice. The MDAY-D2 tumor originally appeared to be an H-2-loss variant tumor of an originally heterozygous tumor growing in AD F_1 x hosts. However, several results cast doubt on its variant nature; for example, MDAY and MDAY-D2 differed in their expression of a wide variety of cell-surface antigens and receptors. If MDAY-D2 is not a variant but is instead a newly induced DBA/2 tumor, the most likely causative agent might be an oncogenic virus harbored by the MDAY cells that is released upon cell death in vivo subsequent to an allogeneic reaction. Although its precise origin is not clear, MDAY-D2 has metastasizing properties that make it desirable for studying the biology of metastasis. (26 refs)

78-7044 T-T Cell Collaboration in Rejection of a Syngeneic SV40-induced Sarcoma in Mice. (Eng) Glaser, M. (Lab. Cell Biology, NCI, Bethesda, MD, 20014); Law, L. W. *Nature* 273(5661): 385-387; 1978.

The concept of T-T cell interactions during cell-mediated immune responses to tumor-associated antigens in vivo was examined. Female BALB/c mice were inoculated sc with mKSA-Tu5 tumor culture cells that had lost their oncogenic potential but had maintained tumor-specific transplantation antigen activity. Additional mice were inoculated ip with mitomycin C-treated (50 $\mu\text{g}/\text{ml}$) Meth-A cells, a methylcholanthrene-induced tumor with strong tumor-specific transplantation antigen activity. In the first experiment, various effector:target cell ratios of lymph node and thymus cells from normal BALB/c mice or mice immunized against mKSA or Meth-A cells plus mKSA or Meth-A cells were injected sc into normal BALB/c mice. No protection against mKSA cells was seen with 25:1 or lower ratios of anti-Meth-A lymph node:Meth-A cells. Thymus cells did not protect against either tumor at any cell number tested. Studies of the ability of immune lymph node and thymus cells to collaborate in the rejection of mKSA cells indicated that injection of immune lymph node or thymus cells alone did not prevent tumor growth, but together they completely inhibited tumor growth. Untreated anti-mKSA immune lymph node cells that could prevent tumor growth lost their activity after treatment with specific anti-Thy-1.2 serum and complement; this indicated that the cell type in the immune lymph nodes needed to neutralize mKSA is T-cell-dependent. Untreated immune lymph node or thymus cells at suboptimal concentrations did not neutralize mKSA when injected alone, but they did prevent tumor growth when injected together. This collaborative effect could be abrogated by pretreatment of either cell type with anti-Thy-1.2 and complement, but not complement alone, before mixing, this indicated that T cells in both lymph nodes and thymus were needed for collaboration. (12 refs)

78-7045 Effect of Generalized Graft-Versus-Host-Reaction on B- and T-Lymphocytes and a Benzpy-

rene-induced Murine Sarcoma. (Eng) Witting, C. (Pathologisches Institut, Westring 17, D-4400 Munster, W. Germany); Hultsch, E. *Z Krebsforsch* 92(3): 255-265; 1978.

The effects of a generalized graft-vs-host reaction (GVHR) on peripheral blood lymphocytes and benzo(a)pyrene (BP)-induced sarcomas were studied in F₁ hybrids of A/Jax female mice and BALB/c males. The GVHR was induced in 3-mo-old hybrid mice by the ip transplantation of A/Jax spleen cells (100×10^6). Twelve months later, BP ($4 \mu\text{g/g}$) was applied sc 1x/wk for 4 wk. Tumor incidence 12 wk after the last application was 74.5% in 200 GVHR mice, compared with 49.5% in 200 control mice. The tumors in the GVHR group were significantly larger and heavier than those in the controls, and metastases were observed in 21% of the mice vs 0% of the controls. In both groups, >95% of the tumors were myosarcomas. The percentage of T lymphocytes declined from 56%-65% in the controls to 36%-45% in the GVHR animals; the percentage of B lymphocytes increased from 21%-30% to 46%-55%. Examination of the marginal zone of the tumors revealed a marked decrease in T cells and total round cell count. There were no changes in B cells in this zone. It is concluded that the GVHR severely impairs cells, probably T lymphocytes or their subgroups, that play an essential role in tumor defense mechanisms. (26 refs)

78-7046 Effect of Splenectomy on B- and T-Lymphocytes and a Benzpyrene-induced Murine Sarcoma. (Eng) Witting, C. (Pathologisches Institut, Westring 17, D-4400 Munster, W. Germany); Hultsch, E. *Z Krebsforsch* 92(3): 267-274; 1978.

The effects of splenectomy (SP) on peripheral blood lymphocytes and benzo(a)pyrene (BP)-induced sarcomas were studied in female hybrids from A/Jax female mice and BALB/c males. The hybrids were splenectomized 3 wk after birth; beginning 10 wk later, the mice received three single doses of $4 \mu\text{g/g}$ BP at weekly intervals. Tumor incidence 12 wk after the last dose was 28.5% in 200 SP animals, and 49.5% in 200 BP controls. Histologically, all tumors of SP mice and 96.9% of those in control mice were myosarcomas, but the tumors were significantly smaller in the SP group. There was a significant decrease in B lymphocytes and an increase in T lymphocytes in the SP mice, compared with BP controls and untreated controls. In the marginal zone of the tumors, there was a decrease in B cells and an increase in T cells but no change in total round cell count. Studies of spleen lymphocytes in 100 untreated hybrid mice revealed a very high proportion of B lymphocytes. The antineoplastic effects of SP may have been due to the B-cell reduction, which allowed T cells to increase proportionally and thus improve host defense mechanisms. (17 refs)

78-7047 Combined Effects of Immune Depression and Carcinogenesis. (Eng) Trainin, N. (Dept. Cell

Biology, Weizmann Inst. Science, Rehovot, Israel); Small M.; Gabizon, A. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY) Vol. 2(part 1), 2404 pp.; 1621-1630; 1978.

The influence of various lymphoid subpopulations on the behavior of transplantable tumors (a simian virus 40-induced and a methylcholanthrene-induced fibrosarcoma; the 3 LI Lewis lung carcinoma) was investigated in inbred mice. When spleen cells from tumor-bearing T mice (thymectomized, irradiated, and injected with thymocytes) were transferred with tumor cells into syngeneic recipients, the incidence of tumor metastases was increased. Spleen cells from B mice (thymectomized, irradiated, and injected with bone marrow cells) did not exhibit this activity. Thymocytes from nonsensitized animals also accelerated the growth of a primary tumor. Fractionation of the spleen cell population from tumor-bearing mice by velocity sedimentation yielded one fraction of tumor-sensitized cells that inhibited the growth of the same tumor and a second fraction that enhanced tumor growth upon transfer. These experiments suggest that subpopulations of lymphocytes with differing characteristics coexist within the spleen and that these subpopulations may exhibit opposing reactivities upon exposure to syngeneic tumor cells. Thus, immunosuppressive agents could bring about contradictory results, depending on whether the tumor-inhibiting or tumor-enhancing subpopulation is impaired. (11 refs)

78-7048 Chemical Modification and Immunogenicity of Membrane Fractions from Mouse Tumour Cells. (Eng) Staab, H. J. (Friedrich Miescher Laboratorium der Max Planck Gesellschaft, Spemannstrasse 37-39, 7400 Tübingen, W. Germany); Anderer, F. A. *Br J Cancer* 38(4): 496-502; 1978.

The effects of several chemicals on the immunogenicity of a crude membrane fraction isolated from mouse STU-D17 tumor cells (STU mouse embryo cells transformed by Rous sarcoma virus) were tested in syngeneic mice. Groups of 10 STU mice were immunized with membrane equivalents corresponding to 10^4 , 10^3 , 10^2 , and 10^1 cells of modified crude membrane fractions of tumor cells or of the crude membrane fractions from DMS-modified tumor cells. A challenge dose of 10^5 viable tumor cells was given sc 14 days after immunization. Compared to 0% tumor-free control animals, immunization with unmodified membrane fraction produced 20% tumor-free animals after 90 days. Immunogenicity was appreciably elevated when the crude membrane fraction was modified by dimethyl sulfate (DMS: 50 mM) and partially elevated when modified by acetic anhydride (50 mM) or glutardialdehyde (200 mM) + [1-ethyl-3(3-dimethylaminopropyl)carbodiimide (20 mM) + methylamine (3 M)]. The membrane

ection treated with DMS produced up to 60% tumor-free animals, and the mean survival time of animals developing tumors showed the greatest increase over controls. However, the membrane fraction from DMS-modified tumor cells failed to produce an immune response, a result that is difficult to explain. For all chemical modifiers, membrane equivalents of 10^2 - 10^4 tumor cells were most effective. Neuraminidase had no apparent effect on the immunogenicity of the tumor cells. The immunogenetic enhancement was specific, as immunization with STU 51A/232B or fetal tissue membrane fractions, even when methylated, had no influence on tumor growth or animal survival. (21 refs)

78-7049 Angioimmunoblastic Lymphadenopathy, Immunoblastic Sarcoma of B Cells. Animal Model: Autoimmune-prone Inbred Armenian Hamster. (Eng) Yernool, G. (Sidney Farber Cancer Inst., 44 Binney St., Boston, MA, 02115); Gagnon, H. J.; Battaglini, A. *Am J Pathol* (1): 209-212; 1978.

An animal model of angioimmunoblastic lymphadenopathy (AIL) and immunoblastic sarcoma of B cells (IBS) was developed using autoimmune-prone inbred Armenian hamsters treated with nitroso compounds. When the 16th- to 17th-generation animals were 482 days old, 25 were treated with methyl nitrosourea (MNU: 70 mg/kg). Within the period 88-390 days after treatment, 12 animals developed massive hepatomegaly and mesenteric lymph node tumors with or without Peyer's patches, pulmonary lesions, and bilateral renal medullary hyperplasia. The 9-yr tumor-free status of the colony was interrupted when 12 untreated young adults developed lesions identical to those noted in the older treated animals. The characteristic presentation of the massive mesenteric lymph node tumors following MNU treatment suggests that these latent B-cell lesions may be selectively responsive to a new and persisting antigen, with the development of AIL when cells are diploid (polyclonal) and the development of IBS when cells are monoclonal. The MNU-associated, spontaneous Armenian hamster AIL and the transplantable IBS feature the characteristic triad of lesions associated with clinical AIL, ie, the multicellularity of proliferating B cells, an extensively arborizing vasculature, and deposits of eosinophilic material. (14 refs)

78-7050 Marek's Disease: Effect of Virus Pathogenicity and Genetic Susceptibility on Responses of Peripheral Blood Lymphocytes to Concanavalin-A. (Eng) Schat, K. A. (Dept. Avian and Aquatic Animal Medicine, New York State Coll. Veterinary Medicine, Cornell Univ., Ithaca, NY, 14853); Schultz, R. D.; Calnek, B. W. In: *Advances in Comparative Leukemia Research 1977. Proceedings of the VIIIth International Symposium on Comparative Research on Leukemia and Related Diseases, held in Amsterdam, The Netherlands on 22-26 August, 1977.* Bentvelzen, P.; Hilgers,

J.; Yohn, D. S., eds. (New York: Elsevier/North Holland Biomedical Press): 503 pp.; 183-186; 1978.

The response of peripheral blood lymphocytes (PBL) to concanavalin A (Con A) was compared using genetic susceptibility to Marek's disease (MD) and virus pathogenicity as variables. A transient depression of the response of PBL to Con A occurred 7 days postinjection of MD-resistant N-line and MD-susceptible P-line chickens with the nononcogenic (SB-1) and oncogenic (GA-5) isolates of MD virus. A permanent depression, starting 2 wk postinjection, developed only in susceptible P-line chickens inoculated with GA-5. (7 refs)

78-7051 Lack of Correlation Between In Vivo Rejection of Syngeneic Fibrosarcomas and In Vitro Non-specific Macrophage Cytotoxicity. (Eng) Evans, R. (Dept. Tumour Immunology, Chester Beatty Res. Inst., Inst. Cancer Res., Clifton Ave, Belmont, Sutton, Surrey SM2 5PX, England); Booth, C. G.; Spencer, F. *Br J Cancer* 38(5): 583-590; 1978.

The relationship between in vitro antitumor activity and in vivo tumor rejection was studied using C57BL mice immunized against two syngeneic benzpyrene-induced fibrosarcomas (FS1 and FS6). After the mice were immunized by sc injection of 10^6 tumor cells and subsequent tumor excision, ip injections of graded doses of FS1 or FS6 cells resulted in a totally specific rejection (in terms of survival). Similarly, the peritoneal inflammatory response (in terms of cell content) was specific; on the peak days of cell production (5-7 days postchallenge) the macrophage content was approx 34%-43%. Conversely, macrophage monolayers prepared from the peritoneal exudates of immunized mice were generally nonspecifically cytotoxic, though occasional specific cytotoxicity was detected. In a 48 hr assay, peritoneal cells from immunized mice lysed ^{125} I-labeled tumor cells in a specific manner, and the loss of lytic potential after pretreatment of cells with anti- θ serum indicated that the reaction was T lymphocyte-mediated. Winn tests further showed that immune peritoneal exudate cells protected normal mice against specific tumor cells, but had no effect on unrelated tumor appearance or growth. It is concluded that the specific rejection of FS1 and FS6 was mediated by T lymphocytes, with possible assistance from macrophages. (16 refs)

78-7052 Host Genetic Factors Influencing the Occurrence of Leukemoid Reaction in BALB/cMk Mice Bearing Transplanted Tumors. (Eng) Kodama, T. (Lab. Pathology, Cancer Inst., Hokkaido Univ. Sch. Medicine, Sapporo 060, Japan); Kawamura, T.; Kobayashi, H. *Cancer Res* 38(12): 4662-4664; 1978.

Hybridization experiments involving BALB/cMk and C57BL/6 mice were carried out to study host genetic factors influencing the occurrence of the leukemoid reaction in

BALB/cMk mice bearing transplanted syngeneic fibrosarcomas. All BALB/cMk mice and all BALB/cMk x C57BL/6 F₁ (CB6F₁) and C57BL/6 x BALB/cMk F₁ (B6CF₁) hybrids, but none of the C57BL/6 mice, were tumor growth-positive (G+) and leukemoid reaction-positive (R+) after fragments of the BALB/cMk tumor CMT-6 were implanted under their back skin. Segregants that were G-,R- were found among the F₂ and C57BL/6-backcross mice. The ratio of G+,R+ to G-,R- mice was 22:8 in the F₂ mice and 14:12 in the C57BL/6-backcross progeny. Neither G+,R- mice nor G-,R+ mice were found. Mice in the parental C57BL/6, F₂, and C57BL/6-backcross groups that were G-,R- were again made tumor-bearing with the C57BL/6 BMT-3 tumor and tested for tumor growth and the leukemoid reaction. G+ mice were observed in all C57BL/6, F₂, and C57BL/6-backcross mice. No R+ mice were found. No BALB/cMk mice, but all C57BL/6 mice with BMT-3 tumor implants were G+. Neither strain with BMT-3 implants was R+. All CB6F₁ and B6CF₁ mice were G+,R+. Segregants that were G-,R- and those that were G+,R- were found among the F₂ and BALB/cMk-backcross mice. Although the ratio of G+:G- mice was 19/7 in F₂ mice, a 12:7 R+:R- ratio was obtained in F₂ mice, seven G+,R- mice, were found. In the BALB/cMk-backcross progeny, the ratio of G+,R+ to G-,R- mice was 14:11. G+,R+ mice were observed in all BALB/cMk, F₂, and BALB/cMk-backcross mice again made tumor-bearing with CMT-6 tumors. These results, the segregation of a positive or negative leukemoid reaction in BALB/cMk mice, were in good agreement with a single dominant gene model and did not fit a two-gene interpretation. The results suggest that occurrence of the leukemoid reaction is regulated genetically in BALB/cMk mice bearing transplanted tumors. (15 refs)

78-7053 Characteristics and In Vitro Growth Influencing Effects of the Spleen Cell Population in a Methylcholanthrene Induced Mouse Sarcoma System. (Eng) Cornain, S. (Dept. Tumor Biology, Karolinska Institutet, S-10401, Stockholm 60, Sweden); Klein, E. *Z Immunitaetsforsch* 154(2): 101-114; 1978.

The effects of immunization on the growth of two transplantable methylcholanthrene-induced fibrosarcomas (MC57 X and MC57 Y) were studied in syngeneic C57Bl mice and their (ABY x C57Bl)F₁ hybrids. For immunization, three injections of 10⁶ x-irradiated tumor cells were given sc at 10-day intervals. Ten days after the last injection, the mice were challenged sc with viable tumor cells (10³, 10⁴, 10⁵, 10⁶, 5 x 10⁶, or 5 x 10⁷ cells); 24 hr before challenge, the mice received 400 R total-body radiation. Preimmunization resulted in complete protection against tumor X, but it enhanced the growth of tumor Y. The enhancement was specific, since the effect was absent in mice pretreated with X cells. The spleens of tumor-bearing animals were enlarged, and they contained a high percentage of blasts; the proportion of complement 3 (C3)- and/or Fc-receptor cells was increased even in the T-cell enriched population. These changes were also observed

to a lesser extent in the lymph nodes. The in vitro growth of tumor cells was inhibited by C3-receptor cells from the spleens of control and tumor-bearing mice and by T-cell fractions from tumor-bearer spleens. The T cells that inhibited target cell growth were detected 14 days after tumor challenge; cells obtained 7 days postinoculation, ie, before tumor growth, enhanced target cell growth. The inhibitory effect of the T cells was nonspecific. The results of the in vitro test reflected only the tumor status of the host and did not relate to preimmunization. (21 refs)

78-7054 Cooperation Between Immune T Cells and Normal Macrophages in the Expression of Tumor Immunity in Chickens. (Eng) Palladino, M. A. (Dept. Pathology, New York Univ. Sch. Medicine, 550 First Ave., New York, NY, 10016); Thorbecke, G. J. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 86-96; 1977.

The possibility that the adoptive tumor-specific immunity expressed in the Winn assay by spleen cells from normal and bursectomized (Bu-x) chickens is mediated by a collaboration between immune T cells and normal recipient monocytes was investigated. Local tumor-specific immunity was transferred into 2- to 4-wk-old recipients with immune T cells from B2/B2 chickens that had rejected B2/B2 fibrosarcoma transplants with the aid of *Corynebacterium parvum*. Immunity was induced and transferred in the total absence of B cells in donors and recipients. Immunity was transferred in normal but not in irradiated or silica-pretreated recipients. Irradiated recipients were reconstituted by (1) iv injection of Bu-x spleen or bone marrow cells and (2) local addition of Bu-x spleen or purified monocytes to the tumor + immune T-cell inoculum. The induction of a delayed hypersensitivity reaction to human gamma-globulin (HGG) in a tumor cell injection site also resulted in tumor immunity. HGG immune spleen cells failed to inhibit tumor cell growth locally unless HGG was also injected in the same site. This immunity, mediated by an adoptive local delayed reaction, could also not be demonstrated in irradiated recipients and thus mimicked tumor-specific immunity in requiring cooperation between immune T cells, antigen, and macrophages. Activation of macrophages through local delayed reactions is concluded to be of paramount importance in obtaining tumor growth inhibition in Winn tests in chickens. (26 refs)

78-7055 Reduced Spontaneous Antitumor Resistance of the Elderly Rat is Restored by *Corynebacterium parvum*. (Eng) Keller, R. (Immunobiology Res. Group, Univ. Zurich, Schonleinstrasse 22, CH-8032 Zurich, Switzerland). *Br J Cancer* 38(4): 557-560; 1978.

The inoculation of DA rats with *Corynebacterium parvum*

increased the in vivo resistance of rats (in terms of survival) aged 30 days or 3-4, 12, or 16-18 mo to the later inoculation of 7,12-dimethylbenzanthracene (DMBA)-induced fibrosarcoma ascites tumor cells. The survival of rats inoculated with syngeneic DMBA-induced tumor cells alone decreased with age and was independent of body wt. However, when the rats were inoculated ip with 3 mg heat-killed strain 2683 *parvum* 1 wk before tumor challenge, local tumor resistance was increased similarly in rats aged 30 days and 3-4 mo; both age groups, *C. parvum* treatment was well-supported and survival time after tumor cell injection was prolonged significantly. Pretreatment with *C. parvum* was much more toxic for rats aged 12 and 16-18 mo and caused the loss of 10%-30% of these animals within 10 days. In the survivors, resistance to tumor challenge varied. In 5/6 experiments, the pretreatment caused a distinct enhancement of local tumor resistance that was sometimes more pronounced than that in younger animals; in one experiment, only minor simulatory effects were noted. (30 refs)

78-7056 In Vivo Anti-tumour Activity of *C. parvum* Stimulated Peritoneal Exudate Cells. (Eng) McBride, W. H. (Dept. Bacteriology, Univ. Edinburgh Medical Sch., Edinburgh, Scotland); Peters, L. J.; Mason, K. A.; Morrow, G.; Milas, L. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 1973-181; 1977.

The antitumor activity of *Corynebacterium parvum*-stimulated peritoneal exudate cells (CP-PEC) was investigated in 3Hf/Bu/E mice in a Winn-type sc transfer assay. The cells inhibited tumor growth when they were admixed with 10^3 or 10^4 fibrosarcoma cells (Fsa) and injected into the mice. When the ratio of CP-PEC:Fsa was 10:1 or higher, there was a significant delay before tumors were detected and a lower final incidence of tumor takes. Normal cells or plastic microspheres interfered with the action of the CP-PEC, presumably by interposing themselves between the target and effector cells. In other experiments, mice were inoculated with 4×10^5 Fsa sc and with three doses of CP ip. There was little activity in the PEC from normal tumor-bearing mice not treated with CP. In contrast, the level of activity in PEC from CP treated normal and tumor-bearing mice was considerable, even at an effector:target cell ratio of 2.5:1. This activity level was maintained in the tumor bearers for some time after injection of CP, but it declined in the normal mice. This suggests that there is some interplay between the stimulus provided by the tumor and that provided by CP, possibly involving a specifically immune T-cell population. There was an unexpected observation of depressed reactivity in the splenic T-cell pool from CP-treated tumor bearers, a finding that contrasts with the enhanced activity of splenic T cells upon iv transfer. This conflict may be due to the different abilities of T-cell subsets to migrate to the tumor site. (19 refs)

78-7057 A Study on Cells Participating in the Antitumour Effect of *Corynebacterium Parvum*. (Eng) Stiffel, C. (Dept. Immunogenetics (U 125 INSERM and ER 70 CNRS), Fondation Curie, Institut du Radium, 26 rue D'Ulm, 75 231 Paris Cedex 05, France); Mazurek, C.; Chalvet, H.; Biozzi, G. In: *The Macrophage and Cancer. Proceedings of the European Reticuloendothelial Society Symposium held in Edinburgh, September 12-14, 1977.* European Reticuloendothelial Society (Edinburgh, Scotland): 448 pp.; 164-172; 1977.

The effects of x-rays and silica on the activity of *Corynebacterium parvum* were studied in two quantitative systems: (1) phagocytosis and antibody synthesis in C3H mice and (2) mortality induced by a transplantable syngeneic mammary carcinoma. Ip injections of 5 mg silica (a specific macrophage toxin) or 500 rads whole-body irradiation inhibited *C. parvum*-induced stimulation of the phagocytic activity of liver and spleen macrophages when given two days before, but not two days after, *C. parvum* administration. The same irradiation dose totally abolished the antibody response to 10^8 sheep red blood cells (SRBC) injected 3 or 10 days later, but partial antibody synthesis occurred when the antigen was injected 20 days after irradiation and agglutination titers were normal in mice immunized at 40 days. Silica had no effect on the antibody response to SRBC or on the adjuvant effect that *C. parvum* supplied to the reaction. Silica injected 2 days before or 4 days after *C. parvum* abolished the bacteria's normal antitumor effect (ie, survival) against the transplanted mammary carcinoma. Irradiation also abolished this effect when administered 3 or 10 days before to *C. parvum*. The antitumor activity of *C. parvum* was restored totally when it was injected 40 days after irradiation. Both silica and x-rays had a similar effect on *C. parvum* antitumor capabilities and macrophage phagocytosis, but only x-rays inhibited antibody synthesis in response to SRBC. (19 refs)

78-7058 Tumor-directed Antibodies in Cancer: A Study of Immune Complexes Eluted from Kidneys of Humans and Experimental Animals with Malignancies. (Eng) Slovin, S. F. (Columbia Univ., New York, NY, 10027). *Diss Abstr Int B* 39(4): 1700-1701; 1978. (no refs)

78-7059 Reduction of Respiratory Tract Binding of Benzo(a)pyrene in Mice by Immunization. (Eng) Moolten, F. (Dept. Microbiology, Boston Univ. Sch. Medicine, Boston, MA, 02118); Capparell, N.; Boger, E. *J Natl Cancer Inst* 61(5): 1347-1349; 1978.

The feasibility of immunizing the respiratory tracts of mice with 5-fluoro-12-methylbenzanthryl-7-acetic acid (FMBAAA)-bovine serum albumin (BSA) conjugates was investigated. Male inbred A/J mice were immunized ip with the FMBAAA-BSA conjugate (0.2 mg antigen) in two doses 2 wk apart. Intranasal immunization (30 μ g antigen in 5 ml

buffer soln was pipetted onto each nostril) was begun 1 wk after the second ip injection and continued 3x/wk for six instillations. Five days after the last dose of antigen, each mouse received two instillations of benzo(a)pyrene (BP) in each nostril 2 hr apart [total dose 92 nanograms (ng)]. The mice were killed 20 hr later, and BP was measured in the nose and tracheal tissues. Total BP bound to these respiratory tissues was 0.0334 ng in animals that received FMBAAA-BSA conjugate, 0.0502 ng in unimmunized mice, 0.0527 ng in BSA-treated mice, and 0.0507 ng in mice treated with an unconjugated mixture of FMBAAA and BSA. γ -Globulin fractions eluted from tracheas of immunized, but not unimmunized, mice exhibited significant BP-binding capacity, indicating that the reduction of bound BP in immunized mice was caused by the interception of BP by antibodies in respiratory secretions. The one-third reduction of BP in the respiratory tracts of the FMBAAA-BSA-immunized mice given 92 ng of BP is equivalent to a reduction in exposure of 30 ng. The data suggest the potential capacity of respiratory tract immunization to cope with significant human exposures to BP and other polycyclic aromatic hydrocarbon carcinogens. (5 refs)

78-7060 Gamma Heavy Chain Disease in Man: Translation and Partial Purification of mRNA Coding for the Deleted Protein. (Eng) Alexander, A. (Dept. Biochemical Sciences, Princeton Univ., Princeton, NJ, 08540); Barritault, D.; Buxbaum, J. *Proc Natl Acad Sci USA* 75(10): 4774-4778; 1978.

Long-term-cultured lymphoid cells from a patient with heavy chain disease continue to produce a protein antigenically identical to the deleted heavy chain disease protein found in the patient's serum. The size of the messenger RNA (mRNA) coding for this protein was determined, and evidence for the presence or absence of translatable light (L)-chain mRNA was sought. The primary in vitro translation product was 1,500-2,000 daltons larger than the polypeptide portion of the cytoplasmic or secreted protein. Methionine was present at the amino terminus of the translation product. The mRNA sedimented at 15.5S on sucrose gradients and, therefore, appears to be smaller than the 17S mRNA coding for normal-sized mouse γ chains. It contained a base sequence that coded for a hydrophobic amino-terminal peptide not found in the cytoplasmic protein. There was no evidence for the synthesis of translatable L-chain mRNA by these cells. The data suggest that the protein resulted from a primary somatic genetic event that gave rise to a cell product bearing a normal aminoterminal sensitive to limited proteolytic digestion. The serum protein thus appears to begin in the hinge region but, in fact, contains a normal heavy chain initiation site. (28 refs)

78-7061 Cancer Related to Asbestos Exposure: Immunological Studies of Patients at Risk. (Eng) Ka-

gan, E. (Dept. Immunology, Natl. Res. Inst. Occupational Diseases, South African Medical Res. Council, Johannesburg, S. Africa); Solomon, A.; Cochrane, J. C.; Beissner, I.; Gluckman, J.; Kuba, P.; Webster, I. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held at the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976*. International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1631-1638; 1978.

Several immunological parameters were evaluated in two groups of asbestos-exposed patients who were at possible risk of developing asbestos-related cancer. Group 1 consisted of 20 patients with asbestos-related pleural thickening; Group 2 consisted of 26 patients with parenchymal asbestosis. Comparatively minor immunological abnormalities were noted among Group 1 patients, and they were generally restricted to isolated disturbances of humoral immunity. All control subjects and all except 2 Group 1 patients exhibited strong cutaneous delayed hypersensitivity reactions to 2,4-dinitrochlorobenzene (DNCB), but 17/26 Group 2 patients manifested cutaneous anergy, indicating defective expression of cell-mediated immunity. In vitro assays also showed significantly impaired cellular immunity in Group 2. Levels of secretory IgA and serum concentrations of IgA, IgG, IgM, and IgE were significantly increased in Group 2, but serum IgA and IgG levels were significantly reduced in Group 1. The percentage and absolute numbers of T lymphocytes were significantly lower in Group 2 compared with controls. Cold-reactive serum lymphocytotoxins were detected in 55% of Group 1 and 81% of Group 2 patients vs 22% of controls. These antibodies showed autoreactivity in 25% of both groups vs 7% of controls. The imbalance between cellular and humoral immunity seen in these patients may be a manifestation of abnormal T-cell/B-cell interaction and may have relevance to the possible causal role of asbestos in the induction of malignancy. (28 refs)

78-7062 Early Increase of Serum Alpha-Fetoprotein in Spontaneous Hepatocarcinogenesis in Mice. (Eng) Jalanko, H. (Dept. Serology and Bacteriology, University of Helsinki, 00290 Helsinki 29, Finland); Virtanen, I.; Engvall, E.; Ruoslahti, E. *Int J Cancer* 21(4): 453-459; 1978.

The concentration of serum alpha-fetoprotein (AFP) was followed by competitive double antibody radioimmunoassay in C3H mice having a high incidence of spontaneous hepatocellular carcinoma. No general elevation of serum AFP levels with age was seen in mice without tumors. With a single exception, mice bearing hepatocellular carcinomas had increased serum AFP levels. In some mice this increase followed a biphasic course. Mice killed within 1 mo of the time when an elevation of serum AFP was first observed had small tumors or no detectable tumor. Premalignant lesions were present in the livers of 11/16 mice that had elevated AFP b

cancer, but only 1/14 mice with normal AFP had such lesions. Autologous antibodies to AFP were produced in a group of C3H mice by immunization with rat AFP. These AFP antibodies reduced the amount of serum AFP but had no effect on the incidence of spontaneous hepatomas. The results suggest that spontaneous hepatocarcinogenesis proceeds through almost the same premalignant lesions as chemically induced carcinogenesis and that an increase in AFP production occurs early during this process, often preceding macroscopic lesions. Repeated testing for AFP in individuals at risk of developing liver cancer might reveal tumors at a curable stage. (24 refs)

7063 A Microassay for the Detection of Tumour-specific Complement-dependent Serum Cytotoxicity Against a Chemically Induced Rat Hepatoma. (Eng) Price, M. R. (Cancer Res. Campaign Labs., Univ. Nottingham, University Park, Nottingham NG7 2RD, England). *Transplantation* 25(4): 224-226; 1978.

A short-term ^{51}Cr -release microassay was developed for the detection of tumor-specific complement-dependent serum cytotoxicity against a transplanted 4-dimethylaminoazobenzene-induced rat hepatoma (D23). The method involves the sequential sampling of supernatants in the wells of microtiter plates containing serum (100 μl), hepatoma cells (10^4 cells/0.1 ml), and guinea pig serum (100 μl) as complement. In a representative test, the complement-dependent cytotoxicity of hepatoma D23-bearer serum and normal rat control serum was determined after 2-, 4-, and 8-hr incubations. The complement-dependent cytotoxicity of tumor bearer serum was present at the three time intervals, even at dilutions of 1/80 or 4 hr of incubation. Using this assay, the serum from rats bearing ip grafts of hepatoma D23 exhibited tumor-specific complement-dependent cytotoxicity for hepatoma D23 cells. Serum from rats bearing sc tumor grafts also exhibited tumor-specific complement-dependent cytotoxicity, in contrast to previous reports. Attempts to use rabbit serum as a source of complement met with variable success. The application of this technique economizes on the time, labor, and reagents required to perform the test in individual plates. (11 refs)

7064 Circulating Immune Complexes in Rats Bearing Chemically Induced Tumours. II. Characterization of Sera from Different Stages of Tumour Growth. (Eng) Witten, K. (West Deutsches Tumorzentrum, Innere Universitätsklinik, Hufelandstrasse 55, D-4300 Essen 1, W. Germany); Price, M. R.; Moore, V. E.; Baldwin, R. W. *Int J Cancer* 22(5): 576-582; 1978.

Sera of WAB/Not rats bearing ip implants of a 4-dimethylaminoazobenzene-induced hepatoma were fractionated

by Sephadex G200 and diethylaminoethylcellulose ion-exchange column chromatography and then examined for their capacity to bind radioiodinated complement C1q to immune complexes, to bind soluble tumor-specific antigen, and to react with antigens on the surface of hepatoma cells. Sera were obtained from rats bearing implants for 3 and 9 days, since these samples display significantly higher and lower capacities, respectively, to bind C1q compared with normal rat serum. Immune complexes were present at both early and late stages of tumor growth; however, inherent limitations in the C1q test prevented their detection in unfractionated sera from late tumor bearers. Fractionated sera from early and late tumor-growth stages displayed significantly greater C1q-binding activity than corresponding normal rat serum fractions in the region 7S-19S, but in unfractionated sera, only samples from rats at early tumor stages exhibited this activity. The results suggest that the detection of immune complexes in unfractionated late tumor-bearer serum by ^{125}I -C1q fixation is masked by the presence of excess tumor-specific antibodies and by a shift from complement-fixing to noncomplement-fixing antibodies. (25 refs)

78-7065 Compared Humoral and Cellular Immune Response to Herpes Simplex (HSV-2) Antigens in Women with Cervical Carcinoma. (Eng) Thiry, L. (Institut Pasteur du Brabant, Brussels, Belgium); Sprecher-Goldberger, S.; Hannecart-Pokorni, E.; Gould, I.; Bossens, M. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 231-243; 1977.

The specific immune status of patients with cervical dysplasia and cervical carcinoma was characterized by determining their specific humoral and cell-mediated responses and comparing the results with those of a control group. The test subjects comprised (1) 30 with a normal cervix, (2) 33 with dysplasia, (3) 32 with cervical carcinoma, (4) 11 cancer patients undergoing radiation therapy, and (5) 35 patients that had been treated (24, surgically). Neutralizing antibodies (ab) to herpes simplex virus type 2 (HSV-2) were studied by neutralization kinetics before and after adsorption of serum samples with *Staphylococcus Cowan A*. Ab remaining in the supernatant were non-IgG ab. These ab were found in 6%, 42%, 66%, 27%, and 6% of the respective five groups. Heparinized blood was obtained from most of these patients. Thymidine incorporation into washed nonpurified lymphocytes was studied in the presence of killed HSV-2 and HSV-1, as well as in the presence of mitomycin C-treated hamster cells transformed by HSV-2 or simian virus 40 or nontransformed cells. Specific stimulation by the HSV-2-transformed cells was obtained in 0%, 24%, 36%, 82%, and 11% of the five groups. Differences among the various groups were less clear-cut when HSV-2 virions were

used as antigens to stimulate the lymphocytes (24%, 37%, 45%, 40%, and 10%, respectively, had lymphocytes responding to the virions). The lymphocyte responses were rarely associated with the non-IgG ab. Some in vivo mechanism must modulate the immune reactions in such a way that the simultaneous presence of non-IgG ab to HSV-2 and lymphocyte responsiveness to this virus is excluded. There was also a negative correlation between the humoral and cell-mediated responses. (16 refs)

- 78-7066 Carcino-embryonic Antigen (CEA) and Alpha-Fetoprotein (AFP) in Cancer-prone Families.** (Eng) Guirgis, H. (Creighton Univ., Omaha, NB); Lynch, H.; Keller, R.; Tomasi, T.; Vandervoorde, J.; Lynch, J.; Rankin, L.; Maloney, K.; Harris, R. In: *Prevention and Detection of Cancer. Proceedings of the Third International Symposium on Detection and Prevention of Cancer Held by the International Study Group for the Detection and Prevention of Cancer in New York, April 26 - May 1, 1976.* International Study Group for the Detection and Prevention of Cancer. (New York, NY): Vol. 2(part 1), 2404 pp.; 1563-1571; 1978.

Carcinoembryonic antigen (CEA) and/or α -fetoprotein (AFP) levels were measured in 698 individuals (521 relatives and 177 spouses) from 11 cancer-prone families. CEA was determined by the Hansen method and AFP by a fluorescence technique. The families were divided into the following categories: (1) breast cancer kindreds (6 families); (2) cancer family syndrome (CFS) kindreds (3 families); (3) malignant melanoma kindred (1 family); and (4) Hodgkin's disease kindred (1 family). Individuals were classified as smokers or nonsmokers. Mean plasma CEA titers/family were 1.11-3.08 ng/ml with standard deviations in the range 0.46-9.13 ng/ml. There were significant intrafamily variations and even greater interfamily variations. Significant elevations of CEA were detected in the spouses of CFS relatives and in nonsmoking spouses of patients from breast cancer-prone families. In the two families tested for AFP, 50% of the individuals were positive for AFP on their lymphocytes. No correlation was found between elevated plasma CEA titers and the AFP test, but there was a significant correlation between a positive AFP test and the suppression of stimulated lymphocytes by the patient's sera. The significance of these results remains to be determined. (17 refs)

- 78-7067 Incidence of Spontaneous Tumours in Neonatally Thymectomized Rats.** (Eng) Dawson, P. J. (Dept. Pathology, Univ. Chicago, Chicago, IL, 60637); Fieldsteel, A. H.; McCusker, J. *Br J Cancer* 38(3): 476-478; 1978.

The spontaneous tumor incidence in neonatally thymectomized (Thy-x) Wistar/Lewis and Buffalo rats was compared with that in intact rats. In addition, 214/1,007 Thy-x Wistar/Lewis rats also were treated with antithymocyte serum (ATS) and/or 250-450 rads of whole-body x-radiation. The most common ATS dose used was 0.5-2.4 ml ip weekly for 3-6 mo beginning at 2-3 mo of age. A total of 33/51 Thy-x Buffalo rats also were irradiated, and 16 of these were given 0.5 ml ATS ip weekly for 6 mo beginning at 2-7 mo of age. Three intact Buffalo and five intact Wistar/Lewis rats received 0.5 ml ATS weekly for 3 mo beginning at 2-7 mo of age. Buffalo rats (24) also were irradiated after they were inoculated with *Mycobacterium leprae* into the foot pads. Tumors were noted in 1/23 male and 10/28 female Thy-x and 2/4 male and 17/32 female intact Buffalo rats. For Wistar rats, the respective figures were 43/517 and 66/490 for the Thy-x animals and 4/65 and 6/43 for intact animals. Breast tumors were the most common tumors, followed by leukemia and fibrosarcomas. It was concluded that the incidence of spontaneous tumors in the two strains was not influenced by prolonged immunosuppression. (11 refs.)

- 78-7068 Immune Response of Prostatic Cancer Patients to Cytomegalovirus-infected and -transformed Human Cells.** (Eng) Laychock, A. M. (Milton S. Hershey Medical Center, Pennsylvania State Univ. Coll. Medicine, Hershey, PA); Gedér, L.; Sanford, E. J.; Rapp, F. *Cancer* 42(4): 1766-1771; 1978.

The possibility of a relationship between cytomegalovirus (CMV) infection and prostatic cancer was investigated. The indirect immunofluorescence (IF) test was used to determine the prevalence of humoral immunity to CMV-induced antigens in 35 patients with prostate cancer, 22 with benign prostatic hyperplasia, 17 with transitional cell carcinoma (TCC) of the bladder, and 18 nonurogenital cancer controls. Sera from the four groups were screened for antibodies to the CMV-transformed cells CMV-Mj-HEL-2 and CMV-Mj-HEL-2,T-1. A high percentage of sera from all test groups reacted when tested against fixed and unfixed preparations of CMV-Mj-HEL-2,T-1 cells at passages 46 and 56, respectively. There were no major differences among the groups when the sera were tested against unfixed cells. With fixed cell preparations, approx 80% of serum specimens from prostatic cancer and bladder cancer patients demonstrated fluorescence. In IF tests against cells infected with strain CMV-Mj, the prostatic cancer group had the fewest patients with titers $< 1:4$ (3%) but the most patients with titers $\geq 1:64$ (66%). Sixty-five percent of the patients with TCC also possessed antibody titers $\geq 1:64$. Thirty-two percent of the patients with benign hyperplasia had antibody titers $\leq 1:4$, and only 32% reacted with CMV-Mj-infected cells in serum dilutions $\geq 1:64$. In the controls, 39% had titers $< 1:4$, 44% had titers between 1:4 and 1:64, and only 22% had titers $\geq 1:64$. A significantly higher number of prostatic cancer patients reacted with the CMV-Mj-infected cells at a serum dilution

4 or higher than did patients with benign hyperplasia or controls. There was no significant difference in reactivity between the prostatic cancer patients and the TCC patients, though a higher ratio of the prostatic cancer group had V-Mj antibodies. When screened against CMV-transfected human cell lines, the reactivity of the sera followed rate of expression of CMV-related antigens of cell lines in these tests. The data enhance the possibility of finding etiologic association between CMV and prostatic cancer. (refs)

PATHOGENESIS

- 78-7069 Chromosomal Evidence for the Transplantability of the Shay Chloroleukemia.** (Eng) Derelan-ko, M. J. (Dept. Biology, 952 Brown Bldg., Washington Sq., New York, NY, 10003); Moorthy, A. S.; LoBue, J.; Meagher, R. C.; Gordon, A. S.; Mitra, J.; Fredrickson, T. N. *J Surg Oncol* 10(5): 441-445; 1978.

Female Long-Evans rats were injected iv with Shay chloroleukemia (SCL) cells, and the resulting tumor cells were studied to determine whether or not SCL is a true transplantable leukemia resulting from colonization of donor leukemic cells. During blast crisis in the recipient rats, the leukemic blast cells were mitotically active in the peripheral circulation, and a large number of mitotic figures were found. Karyotype analyses of the SCL tumor cells used to induce the leukemia demonstrated the presence of X and Y chromosomes. Similarly, all 180 metaphase figures of leukemic blast cells from the peripheral circulation of female rats inoculated with SCL showed the X and Y chromosomes. The data demonstrate that transmission of SCL is a result of donor cell colonization and that SCL can be considered a true transplantable leukemia. Viruses described in SCL by other workers are probably not involved in the transmission of this leukemia. (20 refs)

- 78-7070 Chromosomes and Causation of Human Cancer and Leukemia: XXVIII. Value of Detailed Chromosome Studies on Large Numbers of Cells in CML.** (Eng) Sonta, S. (Roswell Park Memorial Inst., 666 Elm St., Buffalo, NY, 14263); Sandberg, A. A. *Am J Hematol* 3: 121-126; 1977.

Bone marrow aspirates, peripheral blood, and, in one case, splenic tissue from six patients with Philadelphia chromosome (Ph¹)-positive chronic myelocytic leukemia (CML) were subjected to chromosomal analyses. Clones with additional chromosome abnormalities (besides a Ph¹ and a missing Y chromosome) were shown to exist in the uncomplicated, chronic phase of CML when a large number of cells (110 to 500) was examined. These abnormalities were not evident during routine cytogenetic study (10 to 50 cells). The abnormalities were an extra Ph¹ chromosome, missing chromosomes 16 and 17, an isochromosome of the long arm of No. 17, and an abnormal chromosome 2. In 5/6 cases, aneuploid clones observed during the examination of 110 to 500 cells during the chronic phase became the dominant ones during the blastic phase. The data indicate that in some cases of CML, a variety of karyotypically abnormal cells is already present in the marrow during the chronic phase and that the quantitative shift in favor of these abnormal cells as a result of their increased proliferative capacity constitutes the

chromosomal aspects of the blastic phase, rather than the de novo genesis of cells with chromosome changes previously not seen in the marrow. (8 refs.)

- 78-7071 An Autopsy Case of Acute Myeloblastic Leukemia with Persistent High Anti-EBV-antibody Titer.** (Jpn) Musashi, M. (Third Dept. Internal Medicine Hokkaido Univ. Sch. Medicine, Hokkaido, Japan); Maekawa, I.; Sakurada, K.; Fujimoto, N.; Noguchi, H.; Shiraiishi, T. *Jpn J Clin Hematol* 19(8): 1079-1085; 1978.

A case of acute myeloblastic leukemia (AML) with persistent high anti-Epstein Barr virus (EBV)-antibody titer is presented. A 62-yr-old woman presented with fatigue, palpitation, and shortness of breath. Physical examination revealed anemia, but there was no hepatosplenomegaly or superficial lymphadenopathy. Examination of peripheral blood showed moderate anemia, thrombocytopenia, and no atypical cells. However, 4.5% of atypical cells were observed in a bone-marrow specimen; these cells were positive for peroxidase activity and Sudan Black B stain and nucleolus staining showed M-type cells. These results prompted the diagnosis of AML. Chromosome study of the marrow cells revealed karyotype (46xx, 5q-). Two mo later, a tumor was found at the middle nasal meatus that proved to be a well-differentiated hemangioma. Examination of the patient's anti-EBV titer revealed a titer of 1:1280 for antibody to viral capsid antigen (anti-VCA) of 1:80 for antibody to erythrocyte antigen (anti-EA). Anti-VCA and anti-EA persisted at high levels (1:640 and 1:320, respectively) throughout the clinical course. After the appearance of the nasal tumor, the number of leukemic cells increased in the peripheral blood and bone marrow, and a marked hepatosplenomegaly developed. Autopsy revealed leukemic cell proliferation and infiltration in the bone marrow, liver, and spleen. The occurrence of AML with high anti-EBV is rare, and the relationship between AML and EBV infection found in the present case is discussed. (27 refs)

- 78-7072 Leukemia in Radiation-treated Patients: Cytogenetic Studies in Eight Cases.** (Eng) Goh, K. (Medical Oncology-Hematology Unit, Monroe Community Hosp., Rochester, NY, 14603); Bauman, A.; Bakemeier, R.; Lee, H.; Woll, J. E. *Am J Med Sci* 276(2): 189-195; 1978.

The case reports and cytogenetic studies are presented of eight patients (6 women, 2 men; age range 17-66 yr) who developed leukemia several years after diagnosis and treatment for an unrelated primary malignancy. These patients originally had a multiple myeloma, a Wilms' tumor, Hodg-

s disease, a seminoma, a breast cancer, or lymphomas (3 refs). All patients received extensive radiation therapy (100-18,329 rads); two were also treated with nitrogen mustard and one each with chlorambucil, cyclophosphamide, and doxorubicin. Cytogenetic studies were performed on all patients by direct methods; and chromosome abnormalities were seen in every patient. Only 42% of the karyotyped metaphases were diploid, and it was quite common to find less than the full diploid complement of chromosomes. The most consistent abnormal chromosomes, present in 91/516 metaphases analyzed, was a small G chromosome replacing the normal G. Other chromosome abnormalities included ring chromosomes, large acrocentric chromosomes, submetacentric chromosomes, pulverized chromosomes, pseudodiploid metaphases, and chromosome breaks. It is suggested that in these patients there was a causal relationship between previous radiation treatment and subsequent development of leukemia. (19 refs)

78-7073 Lymphoblastoid Cell Lines from Patients with Chronic Lymphocytic Leukemia: Identification of Tumor Origin by Idiotypic Analysis. (Eng) Hurley, J. N. (Rockefeller Univ., New York, NY, 10021); Fu, S. M.; Kunkel, H. G.; McKenna, G.; Scharff, M. D. *Proc Natl Acad Sci USA* 75(11): 5706-5710; 1978.

A large number of continuous lymphoblastoid cell lines were derived from the peripheral blood mononuclear cells of two male chronic lymphocytic leukemia patients with monoclonal IgM bands in the serum. Anti-idiotypic antisera obtained against the isolated IgM band proteins of both patients showed that the serum IgM band, the membrane IgM on the leukemic lymphocytes, and the intracellular IgM in the plasma cells were idiotypically identical. The idiotypic determinants thus constitute tumor-specific antigens. Surface and intracellular immunofluorescence studies using the idiotypic antisera showed that certain cell lines from each patient were derived from the leukemic cells and others were derived from individual normal B lymphocytes. The leukemic lines contained different percentages of lymphoid cells with the idiotype-specific membrane immunoglobulin (Ig) and different percentages of plasma cells with intracellular Ig of the same specificity. Hemagglutination-inhibition analyses of cell line supernatants also demonstrated specific Ig synthesis. Aside from Ig specificity, there were no differences between the leukemic lines and those derived from normal cells. After approximately 6 mo of continuous culture, one leukemic cell line was cloned in soft agarose. The cloning efficiency was approximately 10%. Immunofluorescence studies of seven clones showed that all were of leukemic origin and that they had higher percentages of cells positive for surface IgM than the parental line. (23 refs)

78-7074 A Case of AML Preceded by Fibrinous Bronchitis During the Preleukemic Phase. (Jpn) Nun-

oue, N. (Second Dept. Internal Medicine, Showa Univ. Sch. Medicine, Japan); Kitamura, K.; Tomoyasu, S.; Asano, Y.; Yokoyama, S.; Tsuruoka, N.; Shimizu, M.; Sano, K. *Jpn J Clin Hematol* 19(9): 1226-1233; 1978.

A case of acute myelogenous leukemia (AML) preceded by the preleukemic phase, which developed following admission for fibrinous bronchitis, is reported. A 41-yr-old man presented with fever and recurrent attacks of dyspnea with expulsion of bronchial casts that lasted for several months and was diagnosed as fibrinous bronchitis. About a month after admission, a few abnormal leukocytes appeared in his blood smear. Bone marrow aspirates revealed: NCC $17.3 \times 10^4/\text{cm}^3$, minimal bactericidal level 45.4%, and prothrombin 12.8%. A diagnosis of AML was confirmed. Review of the blood count from the onset of fibrinous bronchitis to the clinical manifestation of AML revealed progressive anemia with anisopoikilocytosis, and an episode of thrombocytosis, monocytosis, and reticulocytosis of unknown cause. The hematologic abnormalities that predated the development of AML were considered to be preleukemic in nature. (32 refs)

78-7075 Quantitative Morphological Evaluation of Basal Lamina Changes During Epithelial Carcinogenesis (Meeting Abstract). (Eng) White, F. H. (Dept. Oral Pathology, Univ. Sheffield, Sheffield, England); Gohari, K. *Clin Sci Mol Med* 55(3): 15P; 1978. (no refs)

78-7076 Evidence for the Progressive Nature of Neoplastic Transformation In Vitro. (Eng) Barrett, J. C. (Div. Biophysics, Sch. Hygiene and Public Health, Johns Hopkins Univ., Baltimore, MD, 21205); Ts'o, P. O. *Proc Natl Acad Sci USA* 75(8): 3761-3765; 1978.

Evidence is presented that neoplastic transformation in vitro is progressive, involving multiple developmental stages. Syrian hamster embryo cell cultures were treated with benzo(a)pyrene (BP) and monitored for the acquisition of in vitro phenotypes associated with neoplasia. Morphological transformation and enhanced fibrinolytic activity were observed within 2 wk and anchorage-independent growth was observed after 6-15 wk. Development of the potential to grow in soft agar did not appear to be related to morphological transformation. One of four spontaneously established Syrian hamster embryo cell lines produced tumors in vivo. None of eight cultures treated with BP for 24 hr produced tumors, but all produced fibrosarcomas in 100% of injected animals after they had acquired anchorage independence in vitro. The data suggest that multiple cellular changes are required for the expression of anchorage-independent growth and that neoplastic transformation in vitro progresses through qualitatively different stages. The results strongly justify the study of oncogenesis in cell cultures as a model for neoplastic transformation in vivo. (24 refs.)

- 78-7077 Genetics of the Large, External, Transformation-sensitive (LETS) Protein: Assignment of a Gene Coding for Expression of LETS to Human Chromosome 8.** (Eng) Owerbach, D. (Roswell Park Memorial Inst., New York State Dept. Health, Buffalo, NY, 14263); Doyle, D.; Shows, T. B. *Proc Natl Acad Sci USA* 75(11): 5640-5644; 1978.

The genetic basis of the large, external, transformation-sensitive (LETS) protein (fibronectin) was analyzed with the use of human-mouse somatic cell hybrids formed from human WI-38 fibroblasts and a mouse L-cell line not expressing LETS. External membrane proteins of these hybrids, which had reduced numbers of human but not mouse chromosomes, were labeled by lactoperoxidase-catalyzed iodination. Cell-surface proteins were identified after sodium dodecyl sulfate/polyacrylamide gel electrophoresis by autoradiography of the dried gel. The LETS protein was identified in parental human cells, and it segregated in the hybrids. The LETS protein segregated concordantly with the chromosome 8 enzyme marker glutathione reductase and human chromosome 8. In addition, dependence on cellular density and trypsin sensitivity were similar for LETS in the hybrid cells and in the human fibroblasts. These findings demonstrate that a gene, *LETS*, encoded on chromosome 8, is responsible for LETS protein expression in humans. Because LETS has been implicated in tumorigenicity and cellular transformation, it is of interest that rearrangement or modifications in the number of chromosome 8 have been associated with certain forms of cancer. (45 refs)

- 78-7078 Hemodynamic Characteristics in Microcirculatory Blood Channels During Early Tumor Growth.** (Eng) Endrich, B. (Dept. AMES-Bioengineering, M-005, Univ. California at San Diego, La Jolla, CA, 92093); Intaglietta, M.; Reinhold, H. S.; Gross, J. F. *Cancer Res* 39(1): 17-23; 1979.

RBC velocity was determined in the microcirculation of the BA 1112 rat sarcoma and in regions located outside the tumor (repairing tissue), which were used as a control and were assumed to be representative of the inflammatory-reparative reaction of a healing wound. Studies were carried out in female Wistar rats of an inbred strain fitted with modified Algire window chambers utilizing television techniques in situ. Observations and measurements were started 14 days after implantation of tumor or adjacent tissue in the chamber and continued for 18 days. RBC velocity in repairing tissue was of the order of 0.80 ± 0.15 (S.E.) mm/sec in terminal arterioles, 0.2 ± 0.09 mm/sec in postcapillary venules, and 0.2 ± 0.1 mm/sec in collecting venules and remained constant during the observation period. By comparison, RBC velocity in terminal arterioles of the tumor tissue increased from 0.72 ± 0.08 to 0.95 ± 0.09 mm/sec and decreased slightly in postcapillary and collecting venules. Vasomotion in terminal arterioles of the malignant tissue could be demonstrated only until day 22 after implantation. Since vasomo-

tion was observed only during the initial phase of tumor growth and the arteriolar RBC velocity increased during the same period, the findings indicate that blood is supplied to mesenchymal tumors by means of dilated arterioles. In adjacent repairing tissue (control), the RBC velocity of postcapillary and collecting venular remained constant. By comparison, RBC velocity decreased in venular outflow vessels of the tumor, suggesting that venous drainage is facilitated during progressive spread of the BA 1112 sarcoma. (22 refs)

- 78-7079 Cell Movement and the Mechanism of Invasiveness: A Survey of the Behaviour of Some Normal and Malignant Cells Implanted into the Developing Chick Wing Bud.** (Eng) Tickle, C. (Dept. Biology as Applied to Medicine, Middlesex Hosp. Medical Sch., Cleveland St. London W1P 6DB, England); Crawley, A.; Goodman, M. *J Cell Sci* 31: 293-322; 1978.

Normal and malignant cells were implanted into the loose mesenchyme of developing chick wing buds to investigate the mechanisms of tumor invasiveness. Two to 3 days later, the distribution of the grafted cells was examined histologically. Cells from mouse lung tumor, rat bladder tumor, and human breast tumor did not invade the mesenchyme, but trophoblastic, sarcoma 180, and neuroblastoma cells and cultured hamster fibroblasts (BHK, PyBHK, Nil 8, HSV Nil 8) did. Cells from embryonic pigmented retina and heart ventricle were invasive. Thus, cell movement may not be a common feature of all invasive tumors. Lack of contact inhibition of movement, although probably involved in the invasiveness of sarcoma 180 cells, did not appear to be necessary for invasion. Cells that exhibited contact inhibition of movement (BHK and PyBHK) were also invasive. Both normal and transformed cells (BHK and PyBHK; Nil 8 and HSV Nil 8) moved into the mesenchyme. Other invading cells, such as trophoblastic, neuroblastoma, and (to a small extent) HSV Nil 8 cells, destroyed the adjacent host tissue, and this may be important in their invasiveness. Trophoblastic cells and the fibroblasts were often elongated along the basement membrane at the ectoderm/mesenchyme border and also closely apposed to the endothelial linings of the blood vessels. Sarcoma 180 and neuroblastoma cells clustered around nerves. The embryonic tissues and neuroblastoma cells were often associated with blood vessels. A striking finding was that carcinoma cells were frequently found positioned within the wing ectoderm on the basement membrane. This affinity of carcinoma cells for epithelium rather than the mesenchyme suggests that the invasiveness of carcinomas involves the same mechanisms as the epithelial invasion of the mesenchyme that occurs during gland development. (77 refs.)

- 78-7080 Banding Studies on Chromosomes in Diffuse "Histiocytic" Lymphomas: Correlation of 14q+ Marker Chromosome with Cytology.** (Eng) Fukuhara, S. (Dept. Medicine, Univ. Chicago Hosp., 950 E. 59th St.

ago, IL, 60637); Rowley, J. D.; Variakojis, D.; Sweet, J. *Blood* 52(5): 989-1002; 1978.

Chromosomes were studied in involved lymph nodes of nine patients with diffuse histiocytic lymphoma. Two of the patients had stage II disease; their tumors were fibrotic and had mitotic cells. One patient was in stage III, and the remaining patients had stage IV disease. The modal chromosome number of abnormal cells from these last seven patients was diploid in two, hyperdiploid in four, and near-triploid in one. Complete banding studies, including peripheral blood and bone marrow, of six cases, and partial analysis of the ninth indicate that (1) every patient had a distinct cell line with common markers, with a few cells showing minor variations; (2) although certain chromosomes (Nos. 1, 2, 3, 9, 12, 14) were structurally affected more often than others, no markers with the same banding pattern were noted among patients; and (3) the cytologic type of lymphoma could be correlated with the karyotype in all seven patients. When the Rues and Collins classification was used, three patients whose tumors were composed predominantly of large noncleaved cells showed a 14q translocation leading to the formation of a 14q+ marker chromosome. This marker was not observed in four patients whose tumors had a majority of cleaved cells. These preliminary results suggest that there are consistent chromosome changes associated with specific subtypes of lymphoproliferative disorders analogous to the Philadelphia chromosome in chronic myelogenous leukemia. (32 refs)

78-7081 Effect of Microtubule Inhibitors on Malignant Invasion In Vitro. (Eng) Mareel, M. M. (Dept. Experimental Cancerology, Clinic Radiotherapy and Nuclear Medicine, Univ. Hosp., De Pintelaan 135, B-9000 Ghent, Belgium); De Brabander, M. J. *J Natl Cancer Inst* 70: 787-792; 1978.

Malignant C3H/3T3 mouse cells MO₁ invaded embryonic heart fragments in an organotypic coculture system in semisolid medium. Malignant invasion was obvious from an irregular boundary between the MO₁ nodule and the heart tissue, the penetration of strands and solitary MO₁ cells into the heart, and destruction of the heart. In this system, at a concentration of 1 µg/ml, the microtubule inhibitors colchicine, demecolcine, vincristine sulfate, vinblastine sulfate, or mefloquine [5-(2-thienylcarbonyl)-1H-benzimidazol-2-yl]carbamate (Nocodazole) totally inhibited malignant invasion. At this concentration the drugs were also mitostatic, which was apparent from the absence of mitoses and from the absence of postmetaphase figures. At a mitostatic dose of 10 µg/ml, 5-fluorouracil (5-FU), cytosine arabinoside, or bleomycin did not interfere with malignant invasion. Combined treatment of the cocultures with 5-FU (10 µg/ml) plus Nocodazole (1 µg/ml) completely inhibited invasion. These cocultures also showed the effective inhibition of mitosis by 5-FU, because Nocodazole-induced chromosome breaks were absent. The reversibility of the anti-invasive effect of a 4-day treatment with Nocodazole

(1 µg/ml) was demonstrated in shaker cocultures with the use of fluid medium. These in vitro experiments indicate that cytoplasmic microtubules are involved in malignant invasion and that cell division and invasion constitute separate characteristics of malignant cells. (32 refs)

78-7082 Evidence that the Malignant Lymphoma of Sjogren's Syndrome is a Monoclonal B-Cell Neoplasm. (Eng) Zulman, J. (Immunology and Arthritis Section, Veterans Admin. Medical Center, 4150 Clement St., San Francisco, CA, 94121); Jaffe, R.; Talal, N. *N Engl J Med* 299(22): 1215-1220; 1978.

Nine patients who developed malignant lymphoma (ML) following Sjogren's syndrome (SS) and antecedent benign salivary gland lesions were studied histopathologically and immunohistologically. Paraffin-embedded tissue blocks of malignant lymphoma were examined in all cases, and SS salivary gland lymphoid lesions in four. The unlabeled antibody-enzyme method (peroxidase antihorseradish peroxidase) was used for immunohistologic analyses. There were six female patients, the average age was 48 yr and the average duration from onset of SS to diagnosis of ML was 10 yr. Two patients received no irradiation or immunosuppressive therapy before ML development. Histologically, the tumors varied within themselves in cellular composition, content of epithelioid histiocytes, presence of plasmacytoid features, and numbers of plasma cells, but 6/9 patients had cytoplasmic immunoglobulin within the ML cells, confirming their B-cell nature. All six of these patients had IgMκ chains exclusively, but only one had rheumatoid arthritis, whereas all three patients who did not have IgMκ chains had rheumatoid arthritis. No tumor cells contained lysozyme, and none gave evidence of phagocytosis. These lymphomas could have arisen coincidentally with Sjogren's syndrome or could represent a stage of B-cell dedifferentiation in which the concentration of intracytoplasmic immunoglobulin falls below a detectable threshold. (23 refs)

78-7083 Familial Hodgkin's Disease. (Eng) Hull, P. J. (Royal Infirmary, Manchester M13 9WL, England); Delamore, I. W. *Postgrad Med J* 54(636): 676-677; 1978.

The occurrence of Hodgkin's disease in a 23-yr-old man, his 22-yr-old sister, and their 13-yr-old cousin is reported. All had mediastinal involvement, and, in each case, the histology was that of nodular sclerosing Hodgkin's disease. (8 refs)

78-7084 Membranous Proliferative Glomerulonephritis and Castleman's Lymphoma. (Fre) Genin, R. (Clinique Medicale, Hopital du Bocage, F. 21034 Dijon)

Cedex, France); Justrabo, E.; Devillebichot, C.; Michiels, R.; Riflé, G. *J Urol Nephrol (Paris)* 84(9): 667-672; 1978.

Castleman's pseudotumor, localized retroperitoneally and associated with membranoproliferative glomerulonephritis, was diagnosed in a 56-yr-old man. This association has never been reported before. A polyclonal plasmacyte population with IgA, IgG, and IgM was found in the tissue surrounding the lymph nodes involved. Disappearance of proteinuria and regression of the nephrotic syndrome were seen after the pseudotumor was removed. Castleman's pseudotumor is very rare; only 200 cases have been reported hitherto. It affects men and women alike, mostly during the second and third decades of life. While a fortuitous association of the two diseases cannot be ruled out, the glomerular affection may be due to the presence of angiofollicular hyperplasia, as are the frequent immunological and hematological manifestations. Thus, the nephropathy may be due to the production of circulating immunocomplexes. According to another hypothesis, the two diseases may have a common etiological factor. Castleman's pseudotumor was found in some cases following vaccination or the resorption of suture material. Bacterial or viral etiology has not been proved. The patient presented here had a facial wound about 2 mo before the onset of glomerulonephritis, which may have been the port of entry of an antigen. (9 refs)

78-7085 Development of the Granulomatous Response in Murine Toxocariasis. (Eng) Kayes, S. G. (Veterans Admin. Hosp., 1310 24th Ave., South, Nashville, TN, 37203); Oaks, J. A. *Am J Pathol* 93(2): 277-294; 1978.

To characterize the cellular evolution of muscle-associated granuloma in murine toxocariasis, *Toxocara canis* eggs were collected from the stools of naturally infected puppies, cultured, checked for the presence of stage 2 (L2) infective larvae, and administered to male HM/ICR mice (1,000 eggs/mouse) by stomach intubation. Necropsies were performed between 11-14, 28-35, and 70-77 days postinfection, and the carcass musculature was examined by light and electron microscopy following appropriate histologic preparation. By day 11, the initial granulomas consisted primarily of eosinophils. By day 14, many of the eosinophils appeared to be dying and undergoing disintegration; the resulting cellular debris was sometimes seen inside macrophages. Two distinct lesions were observed during the 28-35 day interval: the first, representing a continuation of the evolving mononuclear progression seen at day 14 and containing predominantly macrophages, was outlined by fibroblasts and enveloped in a distinct collagenous capsule; the second lesion day contained foci of polymorphs and mononuclear cells similar to those seen at 11-14 days. By 77 days, the granulomas had developed into fibrotically encapsulated epithelioid lesions surrounding the larva. The results indicate that infection by this parasitic larvae nematode progresses from an inflammatory reaction to a loose eosinophil-containing exudate, and, finally, to a

compacted, encapsulated granuloma, a situation likened to hepatic granuloma and schistosome egg granuloma. (36 refs)

78-7086 Studies on a Japanese Burkitt Lymphoma. Part 2: Serial Transplantation of a Japanese Burkitt Lymphoma Cell Line in Hamsters. (Jpn) Kishimoto, I. (Dept. Internal Medicine, Okayama Univ. Medical School, Okayama, Japan). *Jpn J Clin Hematol* 19(9): 1186-1191; 1978.

An Epstein-Barr virus genome-free Japanese Burkitt lymphoma line (JBL) was transplanted ip for 10 serial passages in newborn Syrian hamsters treated with antilymphocyte serum. All the hamsters developed invasive tumors and massive ascites. The hamster-passaged line maintained a characteristic starry-sky pattern closely resembling that of human biopsy material. Some of the animals developed not only bone marrow invasion but also a leukemic blood picture. Since the JBL line was converted to an ascitic form, its serial passage was greatly facilitated. (13 refs)

78-7087 Possible Role of Connective Tissue in Epidermal Neoplasia. (Eng) Mitrani, E. (Dept. Medicine, Welsh Natl. Sch. Medicine, Heath Park, Cardiff, Wales). *Br J Dermatol* 99(3): 233-244; 1978.

Interactions between epidermal cells were defined within a proposed mathematical model of mammalian skin. Examination was made of how epidermis retains its mass both normally and after various disturbances and how this mechanism may fail, as in neoplasia. The model assumes that the lower the epidermal layer (ie, nearer the dermis), the higher the probability of a cell in that layer to enter mitosis. Computer tests of the model suggested that in highly proliferating epidermis, competition for cell space in the basal layer may be sufficient to generate considerable forces in the papillary dermis. According to data on human and pig epidermal hyperplasia, basal cells are submitted to considerable lateral forces and these and not dermal hyperplasia or dermal edema are the forces responsible for the increasingly folded dermoepidermal junction. In the condition of a persistently high mitotic rate, the model remains stable only if new connective tissue (collagen) synthesis is not induced by the developing papillary tension. New collagen tissue formation relieves the stress only temporarily; then the epidermis is in a situation similar to the one prevailing before synthesis began, except that it has induced a given amount of dermal growth. Thus, a self-expanding system emerges. Clearly, collagen synthesis plays an important role in epithelial neoplasia. (38 refs)

78-7088 A Causal Relation Between Bowen's Disease and a Lewisite Scar. (Ger) Krause, H. (Abteilung Dermatologie der Medizinischen Fakultät, Technische Universität München, Germany).

Hochschule, Goethestrasse 27-29, D-5100 Aachen, W. Germany); Grussendorf, E. I. *Hautarzt* 29(9): 490-493; 1978.

A 22-yr-old woman developed Bowen's disease of the right lower leg 8 yr after accidental contact of that area with Lewisite (mustard gas). The tumor excision was followed by a local recurrence 2 yr later. (25 refs)

78-7089 Basal Cell Epithelioma in a Vaccination Scar. (Eng) Hazelrigg, D. E. (Section Dermatology, Veterans Affairs Medical Clinic, 421 Chestnut St., Evansville, IN, 47713). *J Dermatol* 17(9): 723-725; 1978.

A 60-yr-old woman developed a superficial basal cell epithelioma (BCE) in a smallpox vaccination scar. She had been vaccinated at 12 yr of age. Two BCE's had been removed from the posterior neck and forehead 2 and 1 yr before the present presented with the lesion described. The latter had regressed gradually over 6 yr. (12 refs)

78-7090 DNA Repair Deficiency in Lymphocytes from Patients with Actinic Keratosis. (Eng) Darub, J. M. (Dept. Biochemistry and Dermatology, University of Glasgow, Glasgow, G12 8QQ, Scotland); Mackie, R.; and J. D. *Bull Cancer (Paris)* 65(3): 357-362; 1978.

DNA repair activity in peripheral blood lymphocytes was measured in 18 patients with actinic keratosis (AK) and 18 matched controls by comparing the incorporation of ³H-thymidine into UV-irradiated cells with that into nonirradiated cells. The incorporation was followed by autoradiography or scintillation spectrometry. The rate of incorporation of ³H-thymidine (5.0 µCi/ml, 18.5 Ci/mmole) into hydroxyurea-treated (1.5 x 10⁻³M) AK lymphocytes measured at different times after irradiation of 20 Joules (J)/meter²(m²) was constantly lower than that into normal cells at all times examined. When UV dose response was studied by measuring total incorporation of ³H-thymidine in lymphocytes at different UV doses 4 hr after irradiation, the repair activity of AK cells was approx 50% that of controls at all UV doses examined. For both cell populations, the repair curve plateaued between 10 and 20 J/m². Autoradiographic analysis of AK lymphocytes after irradiation at 5.0 and 20 J/m² determined the av UV-induced DNA repair synthesis to be 47.7% and 48.9% of normal lymphocytes, respectively. Measurement of the differential of total incorporation of ³H-thymidine into hydroxyurea-treated and untreated patient and control lymphocytes after 20 J/m² irradiation revealed a DNA repair rate of 41%-56% that of normal controls. The results of using two different analytical methods to examine DNA repair are quite similar and show that the rates of repair in AK cells are all in the range 38-63% that of normal cells. (12 refs)

78-7091 DNA Repair in Conditions Associated with Malignancy: Aging and Actinic Keratosis. (Eng) Ringborg, U. (Radiumhemmet, Karolinska Hosp., S-104 01 Stockholm 60, Sweden); Lambert, B.; Swanbeck, G. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): pp. 1193; 39-52; 1977.

UV light-induced DNA excision repair was studied in two conditions associated with malignancy, aging and actinic keratosis, in an attempt to clarify the relationship between a decreased capacity for DNA repair and malignant disease. WBC from 48 healthy subjects aged 13-94 yr were irradiated with 3.2, 6.4, 9.6, or 19.2 joules/m² UV light and incubated with ³H-thymidine in the presence of hydroxyurea. There were great variations in max incorporation of ³H-thymidine among individuals, and they were considered biological in origin. For the three higher UV doses, DNA repair synthesis was significantly lower in subjects 60-94 yr old than in subjects 13-59 yr old. The av DNA repair capacity decreased by about 30% between 20 and 90 yr of age. WBC from 10 patients with actinic keratoses (5 men, 5 women aged 53-81) and from 10 healthy controls of the same age range were subjected to the same treatment as above. The capacity for DNA repair synthesis was 30% lower in the actinic keratosis patients than in the controls. The possibility that the reduced capacity for DNA repair in aging and actinic keratosis predisposes an individual to malignant disease is discussed. (14 refs)

78-7092 Posttraumatic Epithelioma. (Ita) Fallica, L. (Clinica Dermosifilopatica, Università di Catania, Catania, Italy); Guarneri, B. *G Ital Dermatol* 113(7/8): 477-479; 1978.

Three patients (two men, one woman, aged 70, 62, and 56 yr, respectively) developed basal-cell carcinoma of the skin after mechanical trauma of the same site. The latency from the trauma to the manifestation of the carcinoma was 7-15 mo. Literature data, as well as the rarity of posttraumatic carcinomas, suggest that the trauma only accelerates the development of the neoplasia as a function of a quantitative modification of the cells that are qualitatively already anaplastic, ie, that trauma acts only as a promoting factor. (13 refs)

78-7093 Hydatidiform Mole as a Complication of Artificial Insemination. (Eng) Stone, S. C. (Dept. Obstetrics and Gynecology, Univ. California at Irvine, 101 City Drive S., Orange, CA, 92668). *Am J Obstet Gynecol* 132(6): 696-697; 1978.

A hydatidiform mole developed in a 22-yr-old woman who

had undergone artificial insemination with fresh donor sperm. A spontaneous abortion occurred at 8 wk gestation, and scanty tissue of molar appearance was passed. The pathology report confirmed the diagnosis of molar pregnancy. (2 refs)

78-7094 Naevoid Basal Cell Carcinoma Syndrome and Charcot-Marie-Tooth Disease: Two Autosomal Dominant Disorders Segregating in a Family. (Eng) Heimler, A. (Div. Human Genetics, Dept. Pediatrics, Long Island Jewish-Hillside Medical Center, New Hyde Park, NY, 11040); Friedman, E.; Rosenthal, A. D. *J Med Genet* 15(4): 288-291; 1978.

A family is described in which 16 members (three generations) have Charcot-Marie-Tooth disease; at least six members also have nevoid basal cell carcinoma syndrome (NBCS), and one member with both disorders has two daughters with NBCS. These two disorders have not been reported previously in the same patient or within one family. A diagnosis of NBCS should be considered in any patient with recurrent dentigerous cysts at an early age. (8 refs)

78-7095 Pathogenesis of Prolactin-secreting Pituitary Adenomas. (Eng) Sherman, B. M. (Clinical Res. Center, Univ. Hosps., Iowa City, IA, 52242); Schlechte, J.; Halmi, N. S.; Chapler, F. K.; Harris, C. E.; Duello, T. M.; VanGilder, J.; Granner, D. K. *Lancet* 2(8098): 1019-1021; 1978.

In a comprehensive multidisciplinary study of pituitary tumors, 42 women (aged 18-54) with amenorrhea and hyperprolactinemia [25-833 nanograms (ng)/ml] related to a pituitary adenoma were studied. Seventy-four percent of these patients developed amenorrhea and/or galactorrhea in immediate association with the use or discontinuation of oral contraceptives (24 women) or postpartum (7 women). All underwent transsphenoidal surgery for resection of the tumor, and there was enough adenomatous tissue for immunocytochemical studies in 35 specimens. Prolactin was localized unequivocally in 31 specimens by immunoperoxidase staining with anti-rat prolactin serum. The mean serum prolactin concentration did not differ in the groups with and without galactorrhea, but it was significantly greater in the 15 patients with adenomas 10 mm or more in diameter (226 ng/ml) than in those with lesions < 10 mm (94 ng/ml). The authors suggest that estrogens, which modulate prolactin secretion in normal humans and animals, can induce the growth and expression of otherwise silent pituitary lesions and that this should be considered a risk of oral contraceptive use. (17 refs)

78-7096 Meningiomas in Five Members of a Family over Two Generations, in One Member Simultane-

ously with Acoustic Neurinomas. (Eng) Delleman, J. V. (Ophthalmogenetic Dept., Netherlands Ophthalmic Research Inst., Wilhelmina Gasthuis, Amsterdam, Netherlands); IJong, J. G.; Bleeker, G. M. *Neurology (Minneapolis)* 28(6): 567-570; 1978.

The familial occurrence of meningioma in five members of a family over a two-generation span is reported. The proband was a 33-yr-old man who had undergone enucleation of the left eye at age 22 yr; a meningioma psammomatous of the optic nerve sheath, with infiltration of the surrounding tissue was found. Two recurrences were noted over the next 5 yr. A sister had a spinal meningioma removed at age 25 and a hyperostotic meningioma removed at age 31. The proband's father and uncle also had meningiomas. None of these family members had evidence of neurofibromatosis. The autopsy report of the paternal aunt who had died at the age of 43 indicated that she had bilateral acoustic neurinomas and multiple meningiomas. A sister of the proband has multiple café-au-lait spots. It is suggested that all these cases are manifestations of neurofibromatosis. (55 refs)

78-7097 Possible Maternal Effect on Severity of Neurofibromatosis. (Eng) Miller, M. (Dept. Medicine and Pediatrics, Univ. Washington Sch. Medicine, Seattle, WA, 98105); Hall, J. G. *Lancet* 2(8099): 1071-1072; 1978.

A review of medical records of patients under 18 yr old seen for signs or symptoms suggestive of neurofibromatosis revealed 62 patients (from 54 families) with the disease who were then assessed for severity of disease and whether the individual was the result of a new mutation or born to an affected father or mother. Patients were considered to have this autosomal dominant disease if they demonstrated café-au-lait spots > 1.5 cm in diameter. Severity of disease was graded on a 0-3 scale based on physical and mental parameters. The expected numbers of new mutations and patients born to affected mothers or fathers (based on gene probabilities and relative fertilities) was compared with the observed cases; 16 patients had new mutations, compared with an expected number of 31, 15 were born to an affected father compared with an expected 11, and 31 were born to an affected mother, compared with an expected 20. The mean severity of disease was highest in those born to affected mothers (2.4), least in those born to affected fathers (0.8), and intermediate in new mutations (1.6). Cases due to new mutations or born to affected fathers were relatively evenly distributed among the four grades of severity, but significantly more of those born to affected mothers had severe complications. The 21 cases with severe complications born of affected mothers tended to present the disease early in childhood. Furthermore, in the six instances in which two affected sibs were born to an affected mother, all suffered the most severe form of complications. It is suggested that the severity observed in cases born to affected mothers is due to some factor in the intrauterine environment produced by the affected mother.

interacts only with fetuses that carry the neurofibrinogen gene. This interaction may be humorally mediated (10 refs)

7098 Ulcer of the Tongue after CCNU Therapy for a Spinal-Cord Tumor. (Eng) Walker, M. D. Brain Tumor Study Group, NCI, Bethesda, MD, 20014; Hardison, E. P.; Scully, R. E. *N Engl J Med* 299(19): 1010-1067; 1978.

A 7-yr-old woman with a history of hepatitis and pelvic tumor 1 yr before admission presented with pain in the arm. She was diagnosed with an intradural-extramedullary, mixed astrocytoma/ependymoma-type glioma of the spinal cord. Over the next 3 yr, she received 12 doses of 1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea because of the growth of malignant glial cells in cerebrospinal fluid cultures. Upon second admission, she developed general debility secondary to anaplastic cell carcinoma, with metastases to cervical lymph nodes, lungs, and pleuras. Anatomical diagnosis also revealed myelinolysis, quiescent myelopathy and cavernous hemangiomas of the liver. (5 refs)

7099 Enzymes of Neutrophils from Patients with Precancerous States of the Larynx. (Eng) Lisiewicz, J. (Dept. Hematology, Inst. Internal Medicine, Cracow Medical Academy, Cracow, Poland); Gierlek, T.; Pilch, J.; Piasa, B.; Namyslowski, G. *Rev Esp Oncol* 25(1): 7-11; 1978.

Levels of β -glucuronidase, alkaline and acid phosphatases, N-acetyl- β -glucosaminidase (NAGA), myeloperoxidase, glycogen, and lipids in the peripheral blood neutrophils of 20 healthy men and 24 men with precancerous states of the larynx (leukoplakia, papillomas, or pachydermia) were compared. The patients and healthy controls did not differ in terms of absolute total neutrophil counts or absolute counts of neutrophils staining for β -glucuronidase, acid phosphatase, NAGA, myeloperoxidase, PAS, or lipids. However, mean values of neutrophilic leukocytosis, the absolute count of alkaline phosphatase-positive neutrophils, and alkaline phosphatase activity were significantly higher in the patients than in the controls. In contrast, intracellular β -glucuronidase activity and lipid content were significantly lower in the patients. (11 refs)

7100 Mucoepidermoid Tumor of the Epipharynx. (Ger) Nowak, R. (Klinik und Poliklinik für Hals-, Nasen- und Ohrenkrankheiten, Wilhelm-Pieck-Universität, Doberanerstrasse 139, DDR-25 Rostock 1, E. Germany); Putzke, H. P. *Arch Otorhinolaryngol (NY)* 221(3): 223-233; 1978.

A mucoepidermoid tumor of the epipharynx was diagnosed by biopsy in a 39-yr-old woman. She developed a local recur-

rence about 1 yr after tumor resection. Histopathological investigation revealed that the primary tumor consisted mainly of undifferentiated cells, plus glandular duct and acinar epithelial cells and epidermoid cells at various stages of maturity. The findings suggest that these tumors originate from pluripotent cells of the transition between the acinus and duct, rather than from major glandular and salivary ducts. They are classified as being of low-grade malignancy. (12 refs)

78-7101 Intracisternal Tubular Inclusions in Nasopharyngeal Carcinoma. (Eng) Prasad, U. (E.N.T. Dept., Faculty Medicine, Univ. Malaya, Kuala Lumpur, Malaysia); Gogusev, J. *J Laryngol Otol* 92(11): 979-989; 1978.

Twenty biopsy specimens from patients with nasopharyngeal carcinoma were examined ultrastructurally for the presence of intracisternal tubular inclusions (ITI). These inclusions were observed in the cytoplasm in eight cases. The tubules were arranged in reticular arrays. Dense particles with an outer diameter of 200 Å were interconnected by light bands, and these aggregates were bound by a membrane that was continuous with the granular endoplasmic reticulum (GER). In five other cases, a slightly different type of cytoplasmic inclusion was found. The inclusion was large and almost spherical, with filamentous aggregates criss-crossing in a haphazard way. The aggregates seemed to be connected to the GER. ITI may be the result of an immunological reaction initiated by injured cells infected with Epstein-Barr virus, which acts as an antigen. (37 refs)

78-7102 Radiation-induced Carcinoma of the Thyroid with Severe Thyrotoxicosis. (Eng) Citrin, D. L. (Dept. Human Oncology, 701C Univ. Hosps., 1300 Univ. Ave., Madison, WI, 53706); Pederson, J.; Rose, D. P.; Carbone, P. P. *Wisconsin Medical J* 77(10): 597-599; 1978.

The case of a 65-yr-old woman with radiation-induced metastatic thyroid cancer and severe thyrotoxicosis is presented. The patient had received radiation therapy to the neck and upper chest at age 8 yr. During the year prior to presentation, there was a rapid increase in the size of a neck mass that had been present for many years. The patient had taken thyroxine intermittently during these years but had taken no thyroid medication for at least 3 yr prior to presentation. The patient presented with complete dysphagia. Hyperkinesia, tremor, and atrial fibrillation suggested hyperthyroidism; this was supported by thyroid function tests, but the patient was unable to swallow the ^{131}I for a radioiodine uptake test. Biopsy of the neck mass revealed a mixed follicular and papillary thyroid carcinoma. The firm, nontender mass measured at least 10 x 10 cm and formed a firm collar around the trachea, which could not be clearly identified. Postmortem examination showed that the left lobe of the thyroid gland measured

10 x 5 cm and contained necrotic areas. The right lobe was also involved, with invasion of the capsule and neck muscles. Histologic examination revealed a well-differentiated follicular and papillary carcinoma with colloid present in the follicles. There was no evidence of hyperplastic normal thyroid tissue. The lungs were filled with metastatic thyroid nodules up to 2 cm in diameter. In previously irradiated patients, hyperthyroidism does not exclude the possibility of thyroid cancer. (6 refs)

78-7103 Morphological Aspects of Parathyroid Transplantation. Clinical Relevancy of Induced Invasive Tissue Growth. (Ger) Klempa, I. (Abteilung für Allgemein- und Abdominalchirurgie, Zentrum der Chirurgie der Universität, Theodor-Stern-Kai 7, D-6000 Frankfurt/Main, W. Germany); Steinau, U.; Frei, U.; Koch, K. M.; Usadel, K. H.; Rottger, P. *Chirurg* 49(11): 704-710; 1978.

A 40-yr-old man with hypercalcemia and increased parathyroid hormone levels due to terminal renal insufficiency underwent total parathyroidectomy following which one of the parathyroid glands (showing typical adenomatous hyperplasia without signs of potential or manifest malignancy) was grafted in the forearm. The autograft started growing rapidly 5 mo after grafting, and the serum calcium and parathyroid hormone levels increased. An autonomous tumor-like adenomatous formation measuring 2.5-3 cm in diameter and weighing 3.1 g was excised 9 mo after the implantation. The parathyroid tissue excised showed solid, relatively cell-rich growth interspersed with giant nuclei. The tumor invaded the vessels of the normal muscular tissue. The findings suggest that induced invasive tissue growth is possible following parathyroid autografting and that only parathyroid tissue without adenomatous hyperplasia should be used for this purpose. (16 refs)

78-7104 Growth of Murine Mammary Tumor Cells in an Artificial Capillary System: Ultrastructural Study. (Fre) Mouriquand, J. (Laboratoire d'Histologie, Cytologie et Cyto-genetique, Faculte de Medecine de Grenoble, 38700 La Tronche, France); Mouriquand, C.; Mermet, M. A.; Louis, J.; Petitpas, E. *Biol Cell (Paris)* 31(1): 27-30; 1978.

A method is described for growing murine mammary tumor cells on an artificial capillary system. The cells were from spontaneous mammary tumors in the PS strain of mice. Actually, the cells had reverted to epithelial morphology since they were in the 162nd passage. The artificial capillary system used copolymers of acrylic or polysulfone permeable to substances of mol wt up to 50,000 or 100,000, respectively. The cells were grown in a medium containing 10% decomplexed calf serum, penicillin and streptomycin. Light and electron microscopy was used to monitor growth of the cells in the wk 3-5. Epithelial clumps could be seen between the

capillaries or clustering against them. Murine mammary tumor virus (MTV) particles were numerous, with A-type particles in the cytoplasm and B-type particle in the vacuoles in the intercellular spaces and free in the culture medium. Intracytoplasmic ductlike vacuoles similar to those described in human breast cancer cells were observed, and it is believed that these have not previously been reported in murine mammary tumor cells. (43 refs)

78-7105 Cytology of Secretions and Aspiration Biopsy. Diagnostic Applications in Mammary Diseases. (Ita) Magni, E. (Servizio di anatomia e istologia patologica, Ospedale Civile S. Maria delle Croci, Ravenna, Italy); Montagna, G.; Tabarri, B. *Pathologica* 70(1007/1008): 495-502; 1978.

Secretion cytology was performed in 1,780 women with mammary secretion, and needle biopsy was performed in 73 women with palpable breast nodes. The secretion cytology was indicative of pathological changes: the cytological changes were rated as grade III in 24 cases; papilloma was diagnosed histologically in 19/24 cases, papillomatosis in 5 and intraductal carcinoma in 1. The cytological findings were rated as grade IV-V in 15 cases: intraductal carcinoma was found histologically in 6 cases and invasive carcinoma in 9. The needle biopsy, performed in 395 women with solid nodes and in 357 patients with cystic nodes, failed to reveal tumor cells in any of the cysts. The reliability of needle biopsy was studied in 184 histologically verified cases: the histology revealed malignant tumors in 75 cases; the cytological findings were concordant with the histology in 62 cases, false negative in 5, and 8 biopsies were unevaluable. In 109 histologically negative cases, the biopsy was correctly negative in 85 cases, false positive in 4, and 20 biopsy specimens were unevaluable. The findings indicate the great diagnostic value of secretion and biopsy cytology in the diagnosis of breast diseases. (10 refs)

78-7106 Prevalence of Hypertension and Diabetes in Breast Cancer: A Case-Control Study in 179 Patients and Age-matched, Non-hospitalized Controls. (Eng) Adami, H. O. (Dept. Surgery, Univ. Hosp., S-750 14 Uppsala, Sweden); Rimsten, A. *Clin Oncol* 4(3): 243-249; 1978.

The prevalence of hypertension and diabetes was investigated in 179 consecutive breast cancer patients (mean age, 63 yr) seen in four Swedish counties during a 5-mo period and 17 age-matched controls. Pertinent information was gathered by questionnaire, hospital records, and by interview. The blood pressure of all subjects was measured, and blood samples were taken for hormone analyses. Thirty-three patients and 28 controls were premenopausal. Hypertension was found in 33.5% of the patients and 32.4% of the controls. The distribution of systolic and diastolic blood pressure in the patients was in close accordance with that in the controls, even when the women were subdivided into pre- and postmenopausal

categories. Age was significantly correlated with diastolic and systolic blood pressure. The use of antihypertensive drugs was similar in the two groups. The prevalence of diabetes was also similar: 10 patients (9 under treatment) and 8 controls (all under treatment). Apparently, there is no association between breast cancer and hypertension or diabetes. (27 refs)

78-7107 Fibrocystic Breast Disease in Oral-Contraceptive Users. A Histopathological Evaluation of Epithelial Atypia. (Eng) LiVolsi, V. A. (Dept. Pathology, Yale Univ. Sch. Medicine, New Haven, CT, 06510); Stadel, V.; Kelsey, J. L.; Holford, T. R.; White, C. *N Engl J Med* 9(8): 381-385; 1978.

A case-control study was performed to determine whether the association between oral contraceptive (OC) use and fibrocystic disease (FD) varies according to the extent of epithelial atypia associated with the latter. The patients, 205 premenopausal women aged 20-44 yr, and individually matched controls had been admitted as in- or outpatients to two Connecticut hospitals during 1971-1973. The frequency of FD was not differentially associated with prior OC use when cases were subdivided according to histologic patterns. However, there were variations in the frequency of FD among long-term pill users compared with nonusers according to the degree of epithelial cytologic atypia being considered. The results support the hypothesis that the use of OC for 2-4 yr or more is associated with a decreased frequency of FD with only minimal epithelial atypia, and not with the more florid forms of this condition. These findings suggest that a spectrum of cystic disease exists and that the long-term use of OC protects against the forms of FD that are not firmly associated with an increased risk of breast cancer, but not against the premalignant forms. 78-7108 Volume and Hyperplastic Lesions of Breast of Japanese Women in Hawaii and Japan. (Eng) Sasano, N. (Dept. Pathology, Tohoku Univ. Sch. Medicine, Sendai, Japan); Tateno, H.; Stemmermann, G. N. *Prev Med* 2(2): 196-204; 1978.

Breast volume and the frequency of ductal hyperplasia were determined in autopsy subjects in Japan and Hawaii. The volume of the total breast (TBV) and of the mammary gland was calculated from specimen radiographs of serially sliced breasts enucleated at necropsy. TBV had a relatively good correlation with the Quetelet index (body wt/height squared) except among Japanese women <45 yr of age. Glandular volume had no significant correlation with the Quetelet index except in Japanese women ≥45 yr. In Hawaiian women, the TBV decreased until 39 yr of age and thereafter showed little change. In Japan, the TBV showed a conspicuous decrease with old age, possibly due to a loss of adipose tissue. In premenopausal women, mean values of glandular breast

volume decreased up to 49 yr of age in parallel with the TBV. The volume density increased slightly from puberty to 39 yr; it then decreased and stabilized at a lower level after 40. Women with premenopausal oophorectomy had volume density values within the standard deviation, but they had a smaller mean value. Women with postmenopausal oophorectomy had generally low values. Epithelial hyperplasia was much more common in Hawaiian than Japanese women after age 30. The Hawaiian women were divided into native-born issei and Hawaiian-born nisei. A total of 19/37 nisei showed epithelial hyperplasia; this incidence (51.4%) was far higher than that in the issei (14.5%) and in Japanese women (18.7%). In Hawaiian women aged ≥45 yr, the volume of the mammary gland, corrected by the Quetelet index, was larger when epithelial hyperplasia was present than when it was absent. Women with premenopausal oophorectomy had no epithelial hyperplasia. (4 refs)

78-7109 Metastases In Vitro: Assays for Cell-release and Invasion (Meeting Abstract). (Eng) Li, A. P. (Cancer Res. and Treatment Center, Univ. New Mexico, Albuquerque, NM, 87131). *Proc Am Assoc Cancer Res* 19: 55; 1978. (no refs)

78-7110 Transformed Cell Lines Susceptible or Resistant to In Vivo Surveillance Against Tumorigenesis. (Eng) Patek, P. Q. (Developmental Biology Lab., Salk Inst., P.O. Box 1809, San Diego, CA, 92112); Collins, J. L.; Cohn, M. *Nature* 276(5687): 510-511; 1978.

Steps involved in the transformation of a normal cell to a malignant one were investigated by transforming normal continuous cell lines in vitro and selecting for transformants by their growth in agarose. The tumorigenicity of the cloned, transformed cell lines was tested in normal and immunodeficient (ID) mice. Based on tumorigenic potential, the cells were divided into three classes: O, growth in agarose only; I, growth in agarose + tumor formation in ID mice; C, growth in agarose + tumor formation in normal and ID mice. Normal fibroblast cells (N) derived from BALB/c, BALB.B, and C57BL/6 embryo cultures were transformed virally (simian virus 40 or Abelson murine leukemia virus) or chemically (20-methylcholanthrene, N-methyl-N'-nitro-N-nitrosoguanidine, 11,12-dihydro-3-methylcholanthrene-11,12-epoxide or 5,6-dihydrobenz(a)anthracene-5,6-epoxide). Of 14 agarose-positive cell clones derived from viral transformation, 2 were classified O, 9 I, and 3 C. Of 21 clones derived from chemical transformation, 2 were classified O, 4 I, and 15 C. Overall, 31/35 agarose-positive clones formed tumors in ID mice; ie, there was an 89% correlation between in vitro growth in agarose and in vivo tumorigenicity. The proportion of I tumorigenic transformed lines was 9/12 for the virally transformed lines and 4/19 for the chemically transformed lines. Expressed in terms of surveillance efficiency, 75% of

the former and 21% of the latter were susceptible to a surveillance mechanism that was impaired in ID mice. It is not known whether all C lines are derived from I intermediates; however, clones that have undergone the mutation N to I require another mutation, I to C, to grow as a tumor in normal mice. Primary pulmonary malignant lymphoma developed in a 57-yr-old woman 20 yr after the onset of systemic lupus erythematosus, the first published case of this association. Microscopy revealed a nodular, poorly differentiated-type non-Hodgkin's lymphoma. (no refs)

- 78-7112 **Needle Tract Implantation in a Case of Needle Biopsy for Lung Cancer.** (Eng) Ichiba, M. (Dept. Surgery, Tokyo Medical Coll., 6-7-1, Nishishinjuku, Shinjuku-ku, Tokyo 160, Japan); Aida, M.; Konaka, C.; Hayata, Y. *Jpn J Clin Oncol* 8(1): 71-73; 1978.

A pulmonary adenocarcinoma was implanted in the tract of a small-bore needle biopsy in a 60-yr-old man. It was diagnosed 19 mo after the original biopsy. This was the first case of tumor cell implantation encountered among a series of 582 biopsies and it is the eighth case reported in the literature. (13 refs.)

- 78-7113 **Etiology of Malignant Pericardial Mesothelioma.** (Ger) Eck, H. (Pathologisches Institut, Städtisches Krankenhaus Höchst, Gotenstr. 6-8, 6230 Frankfurt 80, W. Germany); Berg-Schlosser, V. *Dtsch Med Wochenschr* 103(44): 1751-1753; 1978.

Malignant mesothelioma of the pericardium was diagnosed in a 45-yr-old man and in a 77-yr-old woman. Mild lung fibrosis and a slightly but significantly increased number of asbestos needles in the pulmonary parenchyma were found in the 45-yr-old man who, being a scrap dealer, may have been exposed to asbestos occupationally; however, other unknown etiological factors must also have been involved. No asbestos bodies were found in the 77-yr-old woman, but hemosiderin, obviously originating from phagocytized erythrocytes, was found in the tumor cells. This phagocytic activity of the mesothelial cells seems to be a proof of the mesothelial origin of such tumors. (9 refs)

- 78-7114 **Epithelial Dysplasia in Cancerous and Noncancerous Esophagi.** (Eng) Sato, E. (Second Dept.

Pathology, Kagoshima Univ. Faculty Medicine, Kagoshima 890, Japan); Tokunaga, M.; Sakae, K.; Mukada, T.; Sasano, N. *Tohoku J Exp Med* 124(2): 117-128; 1978.

The prevalence, severity, distribution, and histology of esophageal dysplasia were studied in 86 grossly normal human specimens obtained at necropsy and in 100 specimens of esophageal carcinoma obtained at surgery. Fifty-four of the necropsy specimens showed dysplasia, 32 from men and 22 from women. Seventeen men and three women showed moderate or severe dysplasia or carcinoma in situ (CIS). The incidence and severity of dysplasia seemed to increase with alcohol and cigarette use, but the results were inconclusive. The incidence and severity also increased with age. Chronic inflammation, glycogenic acanthosis, and hyperplasia of the duct epithelium were observed frequently, but they were not significantly related to the incidence of dysplasia. Most of the surgical specimens showed a more advanced dysplasia. Those that showed extensive dysplasia tended to have a mosaic pattern of CIS and dysplasia. Carcinoma and extensive dysplasia was found in 24 instances, carcinoma and multifocal dysplasia in 46. Of the 24 cases that did not have treatment prior to surgery, 15 showed dysplasia coexisting with the carcinoma, and 19 showed multicentric foci of carcinoma. The invasive carcinoma sometimes did not show a sharp demarcation from the surrounding mucosa, especially in cases involving well-differentiated squamous cell carcinoma. The results indicate that dysplasia plays a significant role as a precursor lesion in esophageal carcinogenesis. (19 refs)

- 78-7115 **Conversion of a Poorly Differentiated Human Adenocarcinoma to Ascites Form with Invasion and Metastasis in Nude Mice: Brief Communication.** (Eng) Takahashi, S. (First Dept. Surgery, Nara Medical Univ., 840 Shijo-cho, Kashihara, Nara 634, Japan); Konishi, Y.; Nakatani, K.; Inui, S.; Kojima, K.; Shiratori, T. *J Natl Cancer Inst* 60(4): 925-929; 1978.

Cells from a poorly differentiated Borrmann Type III adenocarcinoma of the stomach of a 70-yr-old man were converted to the ascites form in nude BALB/c mice. The tumor cells were passaged sc in nude mice following removal from the patient. At passage 9, the histology of the cells was similar to that of the original tumor; 10^7 cells were then injected ip into nude mice. The injection resulted in ascites carcinoma with invasion (carcinomatous peritonitis) and liver metastasis. Serial transfers of 1.5×10^5 dispersed cancer cells into the peritoneal cavity of nude mice converted this adenocarcinoma to an ascites form. Hemorrhagic ascites accumulated within 3 wk at the first passage and 4-6 wk in serial passages. Carcinomatous peritonitis occurred consistently in the diaphragm, mesenteries, omentum, and pancreas; metastases were seen in the liver and spleen. Iv injection of 6×10^5 cells at ascites passage 3 into nude mice produced metastatic lesions in the lung and heart. The histology of the invasive and metastatic lesions was similar to that of the original tumor. (8 refs)

8-7116 **Relationship Between Gastric Polyps and Gastric Mucosa.** (Cze) Mertl, L. (I. vnitřní klinika katedry dětského lékařství, Fakultní nemocnice Pod Biskupem, V Uvalu 84, Prague 5, Czechoslovakia); Gregor, O. *Československá Lek 24(9): 842-847; 1978.*

The gastric mucosa and gastric secretion were studied in 74 patients with gastric polyps. Malignant (carcinomatous) polyps were found in 19 patients, adenomatous polyps in 25, hyperplastic polyps in 24, eosinophilic granulomas in 2, fibromas in 2, hemangioma and neurinoma in 1 each. The gastric mucosa was normal in 7 patients with benign polyps; superficial gastritis was found in 10 patients with benign and 2 with malignant polyps, atrophic gastritis in 31 patients with benign and 10 patients with malignant polyps, and atrophic gastritis with metaplasia in 7 patients with benign and malignant polyps each. Histamine-resistant achlorhydria was found in 38 patients with benign polyps and in 18 patients with malignant polyps. The findings indicate that chronic inflammation is a primary process in the pathogenesis of mucosal polyps, the polyp being a secondary, local manifestation of gastric mucosa disease. Chronic inflammation also appears to lead to the development of hyperplastic adenomas. The findings suggest a relationship between alterations in the gastric mucosa and tumor growth in the stomach. (24 refs)

8-7117 **'Small Intestinal Type' and 'Colonic Type' Intestinal Metaplasia of the Human Stomach, and Their Relationship to the Histogenic Types of Gastric Adenocarcinomas.** (Eng) Teglbjaerg, P. S. (Inst. Pathology, Odense Univ. Hosp., DK 5000 Odense, Denmark); Nielsen, H. O. *Acta Pathol Microbiol Scand [A] 86(5): 351-355; 1978.*

The frequency of different histochemical types of intestinal metaplasia (IM) was compared in patients with gastric carcinomas of presumed intestinal histogenesis and patients with tumors of nonintestinal histogenesis. Operative specimens were collected from 27 consecutive patients undergoing surgery for stomach cancer. Seven tumors were classified as intestinal cell carcinomas, 6 as pylorocardiac gland carcinomas, 3 as mucous cell carcinomas, and 1 was unclassifiable. Small intestinal type IM, identified by the staining of goblet cells with alcian blue pH 2.6-PAS, was present in all 24 stomachs with IM. Colonic type IM, identified by the reaction of goblet cells with periodate-borohydride/KOH/PAS, was found in scattered IM foci in 11 cases. The frequency of the latter type was significantly greater in stomachs with tumors of intestinal histogenesis than in those with tumors of nonintestinal histogenesis (ie, intestinal cell carcinomas vs pylorocardiac carcinomas). It is suggested that colonic type IM may have a premalignant potential and that the small intestinal type is merely of a reactive character. (18 refs)

78-7118 **Genetic and Communicable Effects on Carcinoembryonic Antigen Expressivity in the Cancer**

Family Syndrome. (Eng) Guirgis, H. A. (Dept. Preventive Medicine/Public Health, Creighton Univ. Sch. Medicine, Omaha, NB, 68178); Lynch, H. T.; Harris, R. E.; Vandevoorde, J. P. *Cancer Res 38(8): 2523-2528; 1978.*

The potential of plasma carcinoembryonic antigen (CEA) as a discriminant of genetic cancer risk was tested in 272 members of six pedigrees manifesting the cancer family syndrome (CFS) and 191 normal controls. In addition, the role of age and duration of cigarette smoking in CEA expression was quantitated, and connubial effects on CEA levels in this syndrome were determined. The CEA distributions per se were transformed to square root CEA (srCEA) to correct for skewness and kurtosis. Duration of smoking and age showed a positive correlation with srCEA level in both family members and controls. The mean srCEA did not differ between family members and controls of the same smoking status. However, when pedigree data were classified by closeness of relationship to cancer patients, there was a significant linear increase in mean srCEA with increasing genetic cancer risk. Unrelated spouses had mean srCEA levels similar to those for the corresponding risk class of their direct-line mates, and the intraclass correlations of srCEA between direct-line relatives and their spouses approached significance when both spouses were concordant for smoking status. It is suggested that there is a genetic-connubial effect on plasma CEA levels that presumably is due to a common environmental agent acting with the degree of genetic predisposition to cancer. An integrative target cell theory is proposed to explain CEA expressivity in the CFS. The model involves the interaction of the CFS genotype with physical factors (cigarette smoking) and a communicable agent (oncogenic virus). (36 refs)

78-7119 **Peutz-Jeghers Syndrome. Intussusception and Associated Malignancies.** (Fre) Besson, A. (Service de Chirurgie A, 1011 CHUV, Lausanne, Switzerland); Delacretaz, F.; Pescia, G.; Vecerina, S.; Saegesser, F. *Chirurgie 104(2): 117-130; 1978.*

The case histories of six patients representing three families with Peutz-Jeghers syndrome (PJS) are presented. Two of the patients developed cancer and eventually died with multiple metastases. The first patient, a 34-yr-old man, had multiple polyps of the stomach and small and large intestines throughout his life, and he had undergone resection of the jejunum and ileum. At the age of 23, a polyp in the sigmoid colon was invaded by an undifferentiated adenocarcinoma. Ten years later, the patient died of complications following surgery for rectal polyps. Hepatic metastases were observed at this time. The other patient, the mother of two sons with the syndrome, died at the age of 48 with multiple metastases from adenocarcinoma of the uterus. She had the cutaneous symptoms of PJS, and x-rays had shown polyps in the ileum and rectum, but the latter had never given rise to clinical symptoms. The literature reports a 5% incidence of gastrointestinal cancers associated with PJS; 1/6 women with the syndrome develop an ovarian tumor, frequently before age 15. (41 refs)

- 78-7120 Chromosomes and B and T Cells in Mycosis Fungoides.** (Eng) Goh, K. (Medical-Oncology Unit, Monroe Community Hosp., 435 E. Henrietta Road, Rochester, NY, 14603); Reddy, M. M.; Joishy, S. K. *Am J Med Sci* 276(2): 197-204; 1978.

Cytogenetic studies were performed using peripheral blood WBC from four male patients (aged 59-78 yr) with mycosis fungoides (MF). The WBC cultures were stimulated with phytohemagglutinin or pokeweed mitogen. Pseudodiploid cells were found in all patients, and they varied between 24% and 42% in each culture. The most consistent chromosomal pattern among the pseudodiploid metaphases was a larger chromosome number 2, the long arm of which appeared longer than that of its homolog. Chromosomal fragments were seen in various proportions in cultures from three patients. The absolute number of lymphocytes from these three patients was lower than that in control cultures. The absolute number of T lymphocytes was also reduced, but only one patient showed a lower proportion of T lymphocytes. Two patients showed a higher frequency but lower absolute number of B cells compared with controls; the frequency and absolute number of B cells were within normal limits in the third patient. The results support the concept that MF is a neoplastic disease, and they suggest that MF and Sezary syndrome are two separate entities. (16 refs)

- 78-7121 Pigmented Xerodermoid: First Report of a Family.** (Eng) Hofmann, H. (Universitäts-Hautklinik Heidelberg, Vosstrasse 2, D-69 Heidelberg, W. Germany); Schnyder, U. W. *Bull Cancer (Paris)* 65(3): 347-350; 1978.

A family concentration of pigmented xerodermoid, a xeroderma pigmentosum variant, is presented. In a second generation of 13 children, 2 men and 2 women patients had typical clinical signs of xeroderma pigmentosum, including increased pigmentation, strong sunburn reactions, an inordinate number of freckles, solar keratoses, and multiple squamous cell carcinoma of the skin in later life; 3/13 children died in early infancy, and 3 of the 6 remaining siblings died of internal malignancies. Their deceased parents had apparently been normal, as were 22 offspring of this second generation, except for marked sun sensitivity and blistering in 2 sons of one patient. One of these men subsequently died of mammary carcinoma. Of 24 members of the fourth generation, 2 had extensive body freckles, but at an age range of 7-25 no other skin aberrations were so far reported. DNA repair mechanisms were investigated in UV-irradiated lymphocytes and epidermal cells of one of the second generation patients. In these cells, the base-excision repair mechanism was normal but the DNA synthesis time was abnormally long, indicative of pigmented xerodermoid. This appears to be the first report of a family concentration of this condition. (8 refs)

- 78-7122 Morphology and Metastatic Nature of Induced Hepatic Nodular Lesions in C57BL x C3H F₁**

Mice. (Eng) Vesselinovitch, S. D. (Dept. Pathology, Pritzker Sch. Medicine, Univ. Chicago, Chicago, IL, 60637); Mihailovich, N.; Rao, K. V. *Cancer Res* 38(7): 2003-2010; 1978.

The metastatic capabilities of well-defined nodular hepatic lesions in mice induced by benzo(a)pyrene (single treatment of 75-150 µg/g), ethylnitrosourea (single treatment of 60-120 µg/g), benzidine-2HCl (continuous treatment of 100 ppm in the diet), and diethylnitrosamine (4 treatments totaling 6-12 µg/g) were evaluated to determine if it is possible to diagnose cancer in the mouse solely by histological examination of the primary lesion. Coded liver and lung tissues from 1,264 treated (C57BL/6J x C3HeB/FeJ)F₁ mice were assessed independently for the presence of primary nodular lesions and metastases, respectively. Primary lesions were classified according to their size, cell morphology, and growth patterns into hyperplastic, adenomatous, and trabecular nodules. None of the 126 mice bearing hyperplastic nodules had pulmonary metastases. Four of 291 mice with adenomatous nodular lesions showed metastases. However, of 733 mice with the trabecular type of nodular lesions, alone or in combination with other lesions, 266 showed pulmonary metastases. The metastases were first detected in mice dying between 51 and 60 wk of age (5%), and the rate increased as a function of age at death, reaching an incidence of 51% in mice surviving > 81 wk. It was concluded that nodules showing trabecular and the more anaplastic solid sheet type of growths represented bona fide hepatocellular carcinomas in the mouse. However, before bioassay data of mouse carcinogenesis are interpreted, the nodular lesions should be classified, the experimental conditions fully assessed, and factors modifying hepatocarcinogenesis considered. - 78-7123 Frequency of Occurrence of Hepatocellular Carcinoma in Patients with Porphyria Cutanea Tarda During Long-Term Observation (Meeting Abstract).** (Eng) Kordac, V. (First Medical Clinic, Charles Univ., Prague, Czechoslovakia). *J Clin Chem Clin Biochem* 16(1): 67; 1978. (no refs)

- 78-7124 Primary Liver Carcinoma: The Possible Role of Sex Hormones (2 Letters to Editor).** (Dut) Zuidema, P. J. (Amsterdam, Netherlands); Houwert, G. J.; Brandt, K. H.; Bronkhorst, F. B. *Ned Tijdschr Geneesk* 122(42): 1634; 1978.

Pathologically increased serum alpha-fetoprotein levels were found in 6/14 patients with primary liver carcinoma. Two other patients with mixed hepatocellular-cholangiolar liver carcinoma were negative. (4 refs)

- 78-7125 Focal Nodular Hyperplasia of the Liver and Oral Contraceptives.** (Eng) Kinch, R. (Depts.

Obstetrics and Gynaecology, Montreal General Hosp., 1650 Cedar Ave., Montreal, Quebec, Canada H3G 1A4); Lough, J. *Am J Obstet Gynecol* 132(7): 717-727; 1978.

Six cases of focal nodular hyperplasia discovered since 1973 at Montreal General Hospital are presented. Two cases are reported in depth; four were published previously and are summarized. The age of the patients ranged from 21 to 45 yr (four were > 40 yr), and all six had taken oral contraceptives for 4-12 yr. Four had taken preparations containing mestranol and one had taken 50 µg ethinyl estradiol + 2.5 norgestrel for 6 yr; the product was unknown in the sixth patient. Each patient had suffered long-term (2-3 yr) upper epigastric discomfort and pain that was mostly located in the area over the hepatic lesion. Upper gastrointestinal series were negative and liver enzyme tests, when performed, were normal. All tumors had the same gross appearance: 3- to 6-cm nodular masses whose resected surface was yellowish and multinodular, with a central fibrous scar radiating into the parenchyma (similar to focal postnecrotic cirrhosis). The normal lobular architecture was replaced by nodules of regenerating parenchyma, with the hepatocytes being arranged in a pseudoacinar pattern. Ductular proliferation was seen along the margins in the vascular stroma. Focal nodular hyperplasia and hepatic adenoma are suggested to be two distinct processes. It is postulated that the estrogen component of the oral contraceptives causes vascular lesions characterized by myointimal hyperplasia and thrombosis, leading to infarct, necrosis, and subsequent nodular hepatic regeneration. Gray-scale ultrasonography is an effective screening method that also aids in a definitive diagnosis. (18 refs)

78-7126 Liver Cell Adenoma Associated with Oral Contraceptive Hormone Therapy. (Eng) Nicolaides, N. J. (133 Leichhardt St., Brisbane, Queensland 4000, Australia). *Med J Aust* 2(6): 274-276; 1978.

The case of a 40-yr-old woman who developed a hepatic adenoma in association with 7 yr of oral contraceptive therapy (norethisterone/ethinyl estradiol) is presented. Upon removal of the tumor, widespread interparenchymal hemorrhage was discovered. Catastrophic intraperitoneal hemorrhage could well have eventuated had the capsule been breached, and needle biopsy of such a lesion may have proved disastrous. (29 refs)

78-7127 A Close Association of Hepatocellular Carcinoma with Cirrhotic Changes Among 275,857 Pathological Autopsy Cases in Japan During 16 Years from 1958 to 1973. (Eng) Miyaji, T. (Japanese Inst. Pathology, Osaka 530, Japan). *Kurume Med J* 24(Suppl): S63-S79; 1977.

The association between hepatocellular carcinoma (HCC) and cirrhotic changes was studied based on 275,857 autopsy cases registered in Japan during 1958 through 1973. The most

frequent malignancy was gastric carcinoma, followed by leukemia, bronchogenic carcinoma, and HCC. During the 16-yr period, 7,002 HCC's and 15,136 cases of cirrhotic changes not associated with HCC or cholangiocellular carcinoma were registered. A gradual increase in HCC's, especially in men, was noted. Seventy percent of the HCC's in men and 53.3% of those in women were associated with cirrhosis, as were 20.7% of cholangiocellular carcinomas in men and 10.7% of those in women. Liver fibrosis was associated with HCC in 1.6% of affected men and 2.0% of the women and with cholangiocellular carcinoma in 8.7% of affected men and 22.0% of the women. Of the cirrroses associated with HCC, 85.8% of those in men and 80.8% of those in women were either unspecified (US) cirrhosis or the Nagayo-Miyake B-type (posthepatic or macronodular) cirrhosis. Among the cirrroses not associated with carcinoma, 50.0% in men and 44.7% in women were of the B and US types. A'-type cirrhosis (transitional between postnecrotic and B type) and B'-type cirrhosis (transitional between fibrosis and B type) were associated with HCC in 29.7% and 23.2% of men, respectively, and in 20.7% and 21.5% of women. The number of postnecrotic and A'-type cirrroses associated with HCC tended to increase over the 16-yr interval. The peak of HCC in men and women was at 55 yr and that of B type and US cirrhosis was at 60 yr. (66 refs)

78-7128 The Histiocytic Origin of the Multinucleated Giant Cells in Myeloma Kidney. (Eng) Factor, S. M. (Dept. Pathology, Albert Einstein Coll. Medicine, Bronx, NY); Winn, R. M.; Biempica, L. *Hum Pathol* 9(1): 114-120; 1978.

The cellular origin of the syncytial multinucleated giant cells in a patient with myeloma kidney disease was determined by light and electron microscopy (EM) and by immunofluorescence. The patient was a 71-yr-old black man with uremia and dysphagia. Even though renal tissue was not fixed for > 20 hr after the patient's death, the multinucleated giant cells appeared well-preserved, contrasting with the marked degeneration of the tubular epithelium (TE). There was a consistent correlation between the presence of giant cells around tubular casts and breaks in the basement membrane. Although casts were present within Bowman's space, they were never associated with giant cells, possibly because the parietal glomerular basement membrane is relatively resistant to penetration by inflammatory cells. One possible source of misinterpretation of a direct transition between the giant cells and the TE was noted by light and EM. Degenerated TE was frequently found in close apposition with giant cells or, in some instances, within spaces enclosed by giant cell cytoplasmic processes. However, EM showed that there was no fusion of cell membranes. There was also a clear difference in staining reactions and a sharp delimitation of cell contours between the giant cells and the TE when the renal tissue was stained for reticulin fibers. Immunofluorescence studies suggested that the multinucleated giant cells phagocytose fragments of proteinaceous casts. The histiocytic origin of the

giant cells was confirmed directly by EM; a lock and key configuration, numerous mitochondria, large numbers of membrane-bound structures, dense bodies, numerous cytoplasmic vesicles, and luminal projections of the plasma membrane were present. It is concluded that the giant cells arise in the interstitial tissues, migrate through breaks in the tubular basement membrane, and engulf and surround intratubular protein casts. (23 refs)

- 78-7129 An Unusual Osteosclerotic Metastasis to the Calcaneus in Basal-Cell Adenocarcinoma of the Kidney in a Child.** (Cze) Mrzena, V. (Ortopedicka klinika, Fakulta detskeho lekarstvi KU, Karlovo nam. 1, 128 00 Prague 2, Czechoslovakia); Belikova, H. *Acta Chir Orthop Traumatol Cech* 45(3): 214-216; 1978.

Osteosclerotic metastasis to the calcaneus was the first symptom of a kidney tumor in a 13-yr-old boy. Basal-cell adenocarcinoma of the kidney was found at surgery. (5 refs)

- 78-7130 Filiform Polyposis.** (Eng) Zegel, H. G. (Dept. Radiology, Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA, 19104); Laufer, I. *Radiology* 127(3): 615-619; 1978.

Filiform polyposis presents a characteristic radiographic appearance of long, filamentous filling defects in an otherwise normal colon. It has been documented in patients with a prior history of ulcerative or granulomatous colitis. In addition, a solitary filiform polyp was discovered in a patient with previously undiagnosed inflammatory bowel disease, and in a patient with Crohn's disease involving the small bowel. Filiform/polyposis may represent a nonspecific sequela of diffuse mucosal inflammation, and it should not be mistaken for a neoplastic form of polyposis. (5 refs)

- 78-7131 Cell Proliferation of the Colorectal Mucosa in Normal Subjects and Patients with Preneoplastic or Neoplastic Pathology of the Colon and Rectum.** (Fre) Maskens, A. P. (Unite de Recherche Cancerologique, Clinique Saint-Michel, Rue de Lantsheere 19, B-1040 Brussels, Belgium). *Acta Gastroenterol Belg* 41(5/6): 226-240; 1978.

Proliferation of cells in the colorectal mucosa was studied by radioactive thymidine uptake in samples from 25 patients (26-71 yr of age; av age 54 yr) with intestinal polyps (14 adenomatous, 9 hyperplastic, 2 villous) and in samples of normal mucosa of 5 tumor-free subjects and 11 patients with colorectal cancer. Distribution of radioactivity was graphed for the lower, middle, and upper thirds of the glandular epithelium in normal and pathological mucosa. In mucosa from normal patients, 66.3% of the radioactivity was recovered in

the lower third, 33.5% in the middle third, and 0.3% in the upper third. In mucosa samples of normal appearance from the cancer patients, 57.7% of the radioactivity was recovered in the lower third, 39.4% in the middle third, and 3.0% in the upper third. In mucosa samples from hyperplastic polyps, 40% of the radioactivity was recovered in the lower third, 93.5% in the lower two-thirds, and 7.5% in the upper third. The location of radioactivity was difficult to calculate exactly in samples from adenomatous polyps due to the morphology and size of the glands; however, av uptake was elevated (23.1% compared with 8.3%) toward the surface regions. Only two samples from villous polyps were analyzed for radioactivity, and the fragile villi made counting difficult. (32 refs)

- 78-7132 The Background Processes in the Development of Endometriosis and Endometrioid Cancer of the Ovaries.** (Rus) Kolosov, A. E. (N. N. Petrov Res. Inst. Oncology, USSR Ministry Health, Leningrad, USSR). *Vopr Onkol* 24(3): 44-50; 1978.

Surgical specimens from 87 patients with ovarian endometriosis and 23 patients with endometrioid carcinoma of the ovaries were analyzed morphologically to determine the changes or background processes leading to these conditions. The group included 61 pre- and 49 menopausal patients. The background lesions included microfollicular cysts (54 patients) and hyperplasia of the ovarian stroma (73 patients: 22 with diffuse, 37 with focal, and 14 with mixed hyperplasia). The premenopausal patients had predominantly follicular cysts and focal hyperplasia, but the menopausal patients had diffuse hyperplasia. Hyperplasia of the endometrium was diagnosed in 41 patients. (16 refs)

- 78-7133 Laurence-Moon-Bardet-Biedl Syndrome and Endometrial Carcinoma.** (Ger) Peiker, G. (Frauenklinik, Friedrich-Schiller-Universitat, Bachstr. 18, DDR-69 Jena, E. Germany); Bohm, W.; Carol, W. *Zentralbl Gynaekol* 100(17): 1126-1130; 1978.

Laurence-Moon-Bardet-Biedl syndrome associated with Stein-Leventhal syndrome and polycystic ovaries was diagnosed in an 18-yr-old obese woman with irregular monophasic menstrual cycles. Endometrial adenocarcinoma was found 5 yr later. Compared with normal values, the total estrogen excretion in the urine was increased (43 $\mu\text{g}/24$ hr), and the 17-ketosteroid excretion was low (2 mg/24 hr). The genesis of the endometrial adenocarcinoma can be explained by the extraglandular (peripheral) aromatization of androgens into estrogens, especially by the transformation of androstenedione into estrone and the absence of estradiol and progesterone during the long-term exposure of the endometrium to estrone. (9 refs)

78-7134 Choriocarcinoma with Metastasis in a Postmenopausal Woman. (Eng) Dougherty, C. M. (Louisiana State Univ. Sch. Medicine, LSU Unit, 5825 Airline Highway, Baton Rouge, LA, 70805); Cunningham, C.; Mickal, A. *Am J Obstet Gynecol* 132(6): 700-701; 1978.

The case of a black woman who had a 34-yr latent period between her last pregnancy (at age 52) and subsequent metastatic choriocarcinoma (ChC) is described. Amenorrhea began after her last pregnancy. Molar remnants, including hydropic villi, retained within the uterus for possibly 34 yr furnished proof of primary trophoblastic neoplasia. Viable, growing ChC in the lungs at autopsy proved the malignant potential of the tumor. (4 refs)

78-7135 Primary Adenocarcinoma of the Vagina: A Case Report with Light and Electron Microscopic Study. (Eng) Navas Palacios, J. J. (Dept. Anatomic Pathology, Ciudad Sanitaria de la Seguridad Social "1 de Octubre," Carretera de Andalucía, km. 5.4, Madrid 26, Spain); de Agustin de Agustin, P. P.; Martinez Tello, F. J. *Acta Cytol (Baltimore)* 22(5): 358-361; 1978.

The case of a 46-yr-old woman with primary vaginal adenocarcinoma unrelated to hormone therapy is reported, and the results of histological and ultrastructural studies are presented. The patient presented with vaginal bleeding after intercourse, and, on examination, an exophytic necrotic mass was found to fill most of the vagina. After removal of the vaginal content, the cervix appeared unremarkable; a 6-cm implantation area was noted on the posterior vaginal wall and fornix. The presence of a primary site other than the vagina was ruled out by lower gastrointestinal tract and chest x-rays, laparoscopy, and rectosigmoidoscopy. The pathologic diagnosis of primary adenocarcinoma of the endometrioid subgroup was made. The ultrastructural features were different from those of clear cell-type vaginal adenocarcinoma. Glycogen aggregates were absent, and the rough endoplasmic reticulum was sparse and did not form stacks. Endocervical type adenocarcinoma was ruled out because of the absence of characteristic mucinous secretory granules. The ultrastructure of the mesonephric nests was different from that of tumors with a true mesonephric origin. The ultrastructural features of renal cell carcinoma were also absent in this case. Because of the ultrastructural features of normal endometrium and endometrial adenocarcinoma are similar to the observations in the present case, it is concluded that the adenocarcinoma was of müllerian origin. (27 refs)

78-7136 Viral Particles in Cervical Condylomatous Lesions. (Eng) Della Torre, G. (Divisione di Oncologia Sperimentale A., Istituto Nazionale Tumori, Via G. Venezian 1, 20133 Milan, Italy); Pilotti, S.; de Palo, G.; Rilke, F. *Tumori* 64(5): 549-553; 1978.

Koilocytosis is a pathologic alteration of squamous epithelial cells of the uterine cervix that is characterized by small nuclei with an indented outline and clumped chromatin surrounded by a halo of transparent cytoplasm. Biopsy specimens from eight patients with condylomatous lesions of the uterine cervix were examined histologically and ultrastructurally. Cervical smears showed koilocytotic atypia in varying numbers of cells in all cases, and malignant epithelial tumor cells were found in one case. In seven cases, the colposcopic pattern was that of early condylomatosis; one case was colposcopically negative except for a small leukoplakia. Ultrastructural examination demonstrated many intranuclear viral particles morphologically identical to papovavirions in the koilocytotic epithelial cells of four patients. The particles were also identical to those of the papilloma virus found in genital condylomata acuminata, suggesting that cervical condylomatous lesions are related etiologically to condylomata acuminata. (8 refs)

78-7137 Early Vulvar Carcinoma. (Eng) Kunschner, A. (Dept. Obstetrics and Gynecology, Magee-Womens Hosp., Univ. Pittsburgh, Pittsburgh, PA, 15213); Kanbour, A. I.; David, B. *Am J Obstet Gynecol* 132(6): 599-606; 1978.

Fifty-eight cases of early vulvar neoplasia recorded in Tumor Registry at Magee-Womens Hospital during 1947-1976 were reviewed. There were 23 cases of squamous cell carcinoma in situ; 16 cases of carcinoma in situ with microinvasion, and 19 cases of occult carcinoma. All these cases were treated surgically with the modality varying from local excision to radical vulvectomy with inguinal lymph node dissection. Regardless of the surgical therapy, none of the patients died of the vulvar malignancy. As part of routine gynecologic surveillance, more critical attention should be given to examination for early epithelial neoplastic lesions of the vulva. This can be accomplished by simple inspection and the use of special diagnostic aids. Biopsy specimens should be reviewed histologically for depth of invasion and the treatment individualized to the patient, with considerations for conservation, especially in younger women. (16 refs)

78-7138 Neoplastic Potential of the Dysgenetic Gonad. Case Report. (Eng) Fayed, J. A. (Truman Medical Center, 2301 Holmes, Kansas City, MO, 64108); Jonas, H. S.; Masterson, B. J. *Mo Med* 75(11): 564-566; 1978.

The case of a 16-yr-old girl with a 46/XY karyotype in whom bilateral gonadoblastoma developed in the gonadal streaks is presented. Gonadal dysgenesis was diagnosed on the basis of the patient's karyotype and lack of secondary sex characteristics. An infantile uterus was found at laparotomy, and streak gonads were identified in the position of normal ovaries. Biopsy disclosed gonadoblastoma, and a total hysterectomy and bilateral salpingogonadectomy were performed. This case il-

illustrates the malignant potential of the dysgenetic gonad. (10 refs)

- 78-7139 Carcinoma In Situ of the Bladder. Report of 10 Cases.** (Fre) Steg, A. (Clinique Urologique, Hopital Cochin, 27 rue du Faubourg Saint-Jacques, 75674 Paris Cedex 14, France). *Ann Urol (Paris)* 12(2): 73-82; 1978.

The symptoms, diagnosis, and therapeutic aspects of carcinoma in situ (CIS) of the urinary bladder are described, and the histology and significance of CIS for invasive carcinoma are discussed in connection with 10 cases of CIS (9 men, 1 woman, aged 51-74 yr). No occupational carcinogenic factors were found. Differentiation between CIS and dysplasia is often very difficult. In simple dysplasia, the number of cell layers is increased. In atypical dysplasia of the epithelium, this change is also associated with nuclear anomalies, while the lack of cohesion and maturation, and giant cells are characteristic of CIS. It is a well-established fact that CIS can evolve into invasive carcinoma; such transformation is seen in 20-50% of all cases, and takes place in 1-6 yr after the diagnosis of CIS. Each invasive carcinoma of the urinary bladder in the 10 patients had a CIS stage. (23 refs)

- 78-7140 Natural History of Papillary Lesions of the Urinary Bladder in Schistosomiasis.** (Eng) Kuntz, R. E. (Dept. Parasitology, Southwest Foundation Res. and Education, San Antonio, TX, 78284); Cheever, A. W.; Bryan, G. T.; Moore, J. A.; Huang, T. C. *Cancer Res* 38(11, part 1): 3836-3839; 1978.

Attempts to autologously and heterologously transfer bladder lesions in monkeys (*Cebus apella*) infected with *Schistosoma haematobium* (1,000 or 2,000 cercariae) are reported, along with the natural history of papillary transitional cell lesions in these animals. The animals were examined by laparotomy and cystotomy 94-164 wk postinfection, and six were chosen for autologous transplant studies, three for heterologous transplant studies. These animals were followed for 14-136 wk postcystotomy and then subjected to necropsy. At cystotomy, variable epithelial hyperplasia was observed in the urinary bladder of the nine monkeys. All biopsy specimens showed marked *S. haematobium* infection. At necropsy, involution of the urothelial hyperplasia had occurred in 8/9 monkeys; the only monkey in which the hyperplasia persisted was also the only monkey with marked active infection. No growth of transplanted epithelium was evident by palpation or by gross or microscopic examination. The results indicate that proliferative transitional cell lesions have restricted growth potential. (15 refs)

- 78-7141 Desmosome Ultrastructure and the Biological Behavior of Chemical Carcinogen-induced Uri-**

nary Bladder Carcinomas. (Eng) Pauli, B. U. (Dept. Pathology, Rush Medical Coll., 1753 W. Congress Parkway, Chicago, IL, 60612); Cohen, S. M.; Alroy, J.; Weinstein, R. S. *Cancer Res* 38(10): 3276-3285; 1978.

The relationship between desmosomes and tumor invasiveness was studied in urinary bladder transitional cell carcinomas induced in male Fischer rats by N-[4-(5-nitro-2-furyl)-2-thiazolyl]formamide (0.2% of diet for 26 wk). The number of desmosomes per unit area of plasma membrane was significantly reduced in the carcinomas. However, the percentage of cell surface area occupied by desmosomes were greater in carcinomas than in controls. This was accounted for on the basis of increases in desmosomal size, which result from squamous differentiation within the tumors. Areas of transitional cell differentiation and squamous differentiation demonstrated an equal capacity for invasiveness. Desmosomes were abundant in invading nests of tumor cells. These findings argue against the idea that decreased intercellular adhesion is a prerequisite for tumor invasion since strong interadhesion is probably a function of the area occupied by the intercellular junctions. (48 refs.)

- 78-7142 On the Etiology of Cancer of the Prostate** (Eng) Stein-Werblowsky, R. (Bikur Cholim Hosp., POB 492, Jerusalem, Israel). *Eur Urol* 4(5): 370-373; 1978.

Experiments demonstrating that the penetration of spermatozoa into the prostatic tissue of Wistar rats can cause abscesses, lithiasis, and carcinoma are presented. Nine of 20 animals developed one of these lesions following the injection of 0.1-0.2 ml of autologous sperm or homologous sperm into the anterior prostate at its junction with the neck of the bladder. (11 refs)

- 78-7143 On the Etiology of Testicular Tumors. An Experimental Study.** (Eng) Stein-Werblowsky, R. (Bikur Cholim Hosp., Jerusalem, Israel). *Eur Urol* 4(1): 57-59; 1978.

The etiology of testicular tumors was examined in Wistar rats. One testicle was extirpated and minced, and 0.2 ml of the resulting suspension was injected into the other testicle. Four of 10 rats developed testicular abnormalities within 32-47 days after injection. One rat had a tumor filling the whole abdomen; the testicle was not enlarged and the tumor, which was readily transplantable to homologous recipients, was apparent only on histological examination of the testis. The testicle of another rat was greatly enlarged, and normal tissue was wholly replaced by tumor. No distant metastases were observed, but the animal died of local spread 3 wk after orchietomy. These results demonstrate that testicular tumors can develop rapidly as a result of autofertilization. It

possible that mature, motile spermatozoa, instead of being discharged into the lumen of the seminiferous tubuli, penetrate the cells of the germinal epithelium. These results also point to a possible mechanism common to all carcinogenic processes, that of fertilization in the sense of nuclear fusion. The function of a carcinogenic agent may be the promotion of nuclear fusion. The chromosome abnormalities, such as excess of chromatin material and aneuploidy generally associated with cancer, lend further support to this hypothesis. (11 refs)

78-7144 Measurement of Urinary Epinephrine in Screening for Pheochromocytoma in Multiple Endocrine Neoplasia Type II. (Eng) Hamilton, B. P. (Dept. Medicine, Veterans Admin. Hosp., 3900 Lock Raven Blvd., Baltimore, MD, 21218); Landsberg, L.; Levine, R. J. *Am J Med* 65(6): 1027-1032; 1978.

A sensitive screening test for the pheochromocytoma component of multiple endocrine neoplasia type II (MEN-II), comparable to the calcitonin radioimmunoassay for medullary carcinoma of the thyroid (MCT), has been lacking. A large family with MEN-II was screened for pheochromocytoma by measuring 24-hr urinary catecholamines as norepinephrine and epinephrine fractions. Pheochromocytomas had been confirmed at surgery in six family members and at autopsy in one. All seven have had associated MCT. In an additional family members, only MCT has been detected. In 5/6 patients treated surgically, the urinary epinephrine fraction was the dominant or sole abnormality, and an epinephrine level $> 20 \mu\text{g}/24 \text{ hr}$, was diagnostic of pheochromocytoma. An increased urinary epinephrine fraction appears to be a characteristic feature of MEN-II pheochromocytomas, and measurement of this fraction a sensitive and reliable screening test in afflicted families. 78-7145 Seminoma in a 12-Year-Old Male with 46 XY/45 XO Karyotype. (Eng) Doll, D. C. (Dept. Medicine, West Virginia Univ. Medical Center, Morgantown, WV, 26506); Kandzari, S.; Jenkins, J. J.; Amato, S.; Jones, B. *Cancer* 42(4): 1823-1825; 1978.

The case of a 12-yr-old boy with pure seminoma in an undescended testis and 46 XY/45 XO karyotype is presented. The presence of the undescended testicle may have been a predisposing factor in the development of the malignancy. The abnormal chromosome constitution might have been an isolated finding with no relation to the patient's malignancy. However, it is possible that the abnormal karyotype was a contributing factor in both the undescended testicle and seminoma. (17 refs)

78-7146 Gonadal Tumors in Testicular Dysgenesis Syndrome. (Rus) Bronshtein, M. E. (Lab. Pathologic Anatomy, Inst. Experimental Endocrinology and Chemistry Hormones, Moscow, USSR); Iur'eva, N. P.; Golubeva, I. V. *Probl Endokrinol (Mosk)* 24(2): 30-35; 1978.

Of 84 patients (1.5-39 yr of age) with testicular dysgenesis syndrome, 26 had gonadal tumors. These tumors were diagnosed in only two patients at clinical examination; the rest were diagnosed at laparotomy. Tumor size ranged from 1.5 x 0.8 cm to 12 x 8 x 7 cm. Of the 26 patients, 10 had both testicles located either in the abdomen (9) or in the inguinal canal (1); 6 of the former had tumors of both gonads. Histologically, the tumors were classified as gonadoblastomas (18) or dysgerminomas (8). (11 refs)

78-7147 Malignant Transformation of Osteoid Osteoma. (Ger) Wahl, H. (Orthopädische Klinik, Medizinische Akademie Magdeburg, Schellingstrasse 3/4, DDR-301 Magdeburg, E. Germany); Dominok, G. W. *Zentralbl Chir* 103(22): 1490-1492; 1978.

An osteoid osteoma of the left tibia was diagnosed and partially resected in a 22-yr-old woman 3 yr after onset of the first symptoms. The symptoms (pain, swelling, and local hyperthermia) recurred 3 mo later. An osteosarcoma of the same site was diagnosed following partial resection performed about 2 yr after the first operation. To date, she remains free from any metastasis. (6 refs)

78-7148 Tissue Culture Studies on Human Giant Cell Tumor and Osteosarcoma. (Eng) Ishii, S. (Dept. Orthopaedic Surgery, Hokkaido Univ. Sch. Medicine, Kita-14-jo, Nishi-5-Chome, Sapporo, Hokkaido, Japan); Yamawaki, S.; Sasaki, T.; Usui, M.; Ubayama, Y.; Minami, A.; Yagi, T. *Int Orthop* 2(1): 77-86; 1978.

The cytological aspects of giant cell tumors (GCT) and osteosarcomas (OS) were investigated in vivo and in vitro. Primary cultures of GCT were successful in 33/41 trials, and 34/33 were transferred serially for more than two subculture passages. Two established lines (G-1 and G-2) were maintained for long-term cultivation. Primary OS cultures were successful in only 22/61 trials, and none of the cultures survived > 10 passages. Although round at initial cultivation, the giant cells became fibroblastlike after several hours; after 8-10 mo of cultivation, G-1 and G-2 became epitheliallike. The ultrastructure of the giant cells became increasingly complex with time in culture, displaying numerous microvilli, well-developed organelles, and free ribosomes, but the ultrastructure of the OS cells in primary culture

was essentially the same as that of the in vivo tumor cells. The GCT began with a normal chromosome complement of 46 and a superficially normal diploid karyotype. In contrast, the OS were characterized by aneuploid modal numbers. The number of polyploid and aneuploid cells in the GCT increased with passage number, resulting in a modal chromosome number of 65 at subculture 325. The lactate dehydrogenase (LDH) isozyme patterns of the GCT showed max activity in fractions IV and V; those of the OS showed max activity in fraction III. The LDH isozyme patterns of G-1 and G-2 showed max activity in fractions III and IV, respectively. In later transfer generations, G-1 and G-2 produced, in Wistar/Mk rats, tumors by sc inoculation and tumor death by iv inoculation. Sarcomatous stromal cells in the sc tumors were enmeshed in the hyaline network, resulting in the formation of osteoid or chondroid tissue. The results strongly suggest that the benign GCT may have become malignant during the long in vitro transfer period. (15 refs)

EPIDEMIOLOGY AND BIOMETRY

8-7149 **Chronic Dental Infections in the Etiology of Glioblastomas (Meeting Abstract).** (Eng) Storbecker, P. (Akerbyvagen 282, Taby/Stockholm, Sweden). *Neuropathol Exp Neurol* 37(5): 695; 1978. (1 ref)

8-7150 **Proliferative State of Blast Cell Progenitors in Acute Myeloblastic Leukemia (AML).** (Eng) Minden, M. D. (Ontario Cancer Inst., 500 Sherbourne St., Toronto, Ontario M4X 1K9, Canada); Till, J. E.; McCulloch, A. *Blood* 52(3): 592-600; 1978.

Blast cell colony formation by WBC from the peripheral blood of 15 patients with acute myeloblastic leukemia was studied. Colony formation by WBC from these patients was influenced markedly by the concentration of media conditioned by the leukocytes (LCM) in the presence of phytohemagglutinin (PHA). At low PHA LCM concentrations, colonies were compact, immobile, and situated at the bottom of the culture dishes. At higher PHA LCM concentrations, colonies were larger and globular in shape, and they floated in the methylcellulose. The former colony morphology was usually associated with peroxidase-negative cells of blastlike morphology that did not form erythrocyte (E) rosettes. Colonies at high PHA LCM concentrations were composed of small cells (resembling normal lymphocytes) that readily formed E rosettes. The major finding is that progenitors of blast cell colonies are predominantly in a rapid cell cycle, as judged by determinations of the proportion of the cycle in the S phase using tritiated thymidine or hydroxyurea as a DNA synthesis-specific inhibitor. Unless there are very unusual distributions of the cells around the cell cycle, the data indicate that the population of cells detected by this assay is rapidly proliferating. The culture assay for blast cell progenitors detects a minority cell population of morphologically identified blasts; this subpopulation has sufficient proliferative potential for colony formation. The observation that blast progenitors are rapidly proliferating is consistent with the view that they serve to maintain the rest of the blast population. (36 refs.)

78-7151 **The Association between Bronchial Cancer Mortality and the Tobacco Industry in Switzerland between 1970 and 1975.** (Fre) Cardis, F. (Lausanne, Switzerland). *Broncho-Pneumologie* 28(1): 29-30; 1978.

Between 1970 and 1975, bronchial cancer mortality in Swiss women increased 41.5%, vs only 27.8% for Swiss men. During this time, mortality due to other malignant tumors de-

creased 8.91% in men but increased 3.62% in women, and mortality from all malignant tumors increased by 13.34% in men and 4.74% in women. The increase in bronchial cancer mortality in women may have been the result of an increase in the number of women smoking cigarettes. (no refs.)

78-7154 **Celiac Disease. II. Differences in Its Course in Survivors and Deceased Subjects, and Tumor Incidence.** (Cze) Dvorak, M. (Interni oddeleni fakultni polikliniky, Karlovo nam. 32, 121 11, Prague 2, Czechoslovakia); Fric, P.; Lojda, Z. *Cesk Gastroenterol Vyz* 32(4): 217-226; 1978.

Thirty-two adults with celiac disease were followed from 1955 to 1975. Thirteen of the 32 patients died. Cardiopulmonary disease was the cause of death in six cases, suicide in one and malignant tumors in six. The tumors included malignant lymphomas (4), bronchogenic carcinoma (1), and gynecological carcinoma (1). One of the survivors developed jejunal adenocarcinoma, which was successfully resected. The tumors were considered to be a late complication of prolonged celiac disease. Gluten-free diets reduced the cancer risk only partly. (18 refs)

- 78-7155 Lung Cancer Mortality in Uranium Miners (Methodological Aspects) (Letter to Editor).** (Eng) Kunz, E. (Inst. Hygiene and Epidemiology, Centre Radiation Hygiene, 100 42 Prague 10, Czechoslovakia); Sevc, J.; Placek, V. *Health Phys* 35(4): 579-580; 1978.

Data from a 1976 epidemiological study of lung cancer mortality in Czech uranium miners were reevaluated for a group of miners entering employment in 1948-1952. The mortality experience was analyzed in terms of number of cases per unit time at risk, which began with entry into the study group and ended at the cut-off date of the analysis. The results of this recalculation show a coincident picture of response to the increase of cumulative exposure, as in the earlier evaluation. Significant differences between observed and expected values of lung cancer were found in all exposure categories with the exception of the lowest one. The differences in the frequency of additional cases among exposure categories were also significant and, contrary to a study on American uranium miners, confirmed the increase in lung cancer incidence in relation to dose from the first category of exposure upward. The recalculation led to some increase in the estimated number of additional cases in higher exposure categories and a decrease in lower categories compared with the earlier treatment. The distortions caused by the earlier method, however, are not large because the Czech miners entered work and exposure in the same relatively narrow 5-yr period and reached the final exposure levels mostly in the first 5 yr of work. Statistical analyses of mortality rates in England and Wales show a sharp rise in lung and bronchial cancer deaths among women aged >45 yr and, since 1961, a moderate decline in the rates among men. Differences in smoking habits may account for some of the differences in mortality among men of different social classes. Proportional mortality rates for stomach, intestinal, and rectal cancer are lower than expected among immigrants from India, with Asians having even lower rates than Indian-born Britons. (9 refs)

- 78-7158 Incidence of Bilateral Tumours in a Population-based Series of Breast-Cancer Patients. I. Two Approaches to an Epidemiological Analysis.** (Eng) Pri-

or, P. (Birmingham Regional Cancer Registry, Queen Elizabeth Hosp., Birmingham, England); Waterhouse, J. A. *Br Cancer* 37(4): 620-634; 1978.

The incidence of second primary breast tumors in the contralateral breast was determined among 21,967 primary breast cancer patients registered with the Birmingham Regional Cancer Registry between 1936 and 1964. The results were based on >90,000 woman-years at risk and 399 second primary tumors. When the data were analyzed by a method that included coincidental tumors, the overall risk of a tumor in the contralateral breast was found to be 3.0 times that of a first primary in the general population. The corresponding risks for the three main age groups (at time of diagnosis of first primary tumor) were 5.6 (15-44 yr), 3.7 (45-59 yr), and 1.8 (≥ 60 yr). When coincidental tumors were excluded from the analysis, the relative risk was found to be 2.4 overall and 5.3, 3.0, and 1.0 for the respective age groups. The level of risk was negatively correlated with age at first primary, and the relative risk remained fairly constant over time. (11 refs)

- 78-7159 Carcinoma of the Breast in Women under the Age of 30 (Letter to Editor).** (Eng) Logan, C. J. (Ulster Hosp, Dundonald, Down, England). *Br Med J* 2(6143): 1023; 1978.

Of a group of 213 breast cancer patients, only 3 were <30 yr old, vs 10 of a previously reported group of 195 patients. a high incidence for this age group. Malignancy was discovered in the three women only upon biopsy. None has developed metastases after several years. (1 ref)

- 78-7160 Carcinoma of the Breast in Women under the Age of 30 (Letter to Editor).** (Eng) Jones, V. (Radiotherapy Center, Velindre Hosp., Cardiff, Wales); Slater, A. *Br Med J* 2(6174): 1300; 1978.

Assessment of the age distribution of breast carcinoma patients referred to a radiotherapy center from 1955 to 1977 showed that the age incidence had not changed markedly during this period. The number of women <30 yr old presenting with breast cancer remained at $\leq 1.1\%$. (no refs)

- 78-7161 Tubular Carcinoma of the Breast. A Study of Frequency.** (Eng) Carstens, P. H. (Dept. Pathology, Univ. Louisville Sch. Medicine, P.O. Box 35260, Louisville, KY, 40232). *Am J Clin Pathol* 70(2): 204-210; 1978.

The frequency of tubular carcinoma of the breast among 409 infiltrating breast carcinomas diagnosed during 1974 in the Louisville, Kentucky, area was determined. This carcinoma was histologically defined as an infiltrating breast cancer con-

sisting of tubular structures separated by an abundant amount of hyalinized stroma. A total of 42 tubular carcinoma cases were identified in women aged 26-84 yr. Five patients had bilateral breast cancer, and in three, the contralateral breast also contained tubular carcinoma. Two patients had multifocal tubular carcinoma. Axillary lymph nodes were available for examination with 36/42 breast specimens, and metastatic foci were found in 6. Three histological types of tubular carcinoma were identified: (1) sclerosing type, characterized by a haphazard arrangement of tubules infiltrating into surrounding fat and connective tissue; (2) pure type, consisting of desmoplastic hyalinized stroma surrounding a few tubular structures; and (3) mixed type, in which at least 75% of the tumor was of the tubular variety. Five patients had the first type (none had involved lymph nodes), 9 had the second type (1 with involved nodes), and 28 had the third type (5 with involved nodes). All 42 patients are alive 2 yr after diagnosis; 2 patients have had recurrences. These findings suggest that this type of breast cancer is not as rare as previously reported. (9 refs.)

78-7162 The Hormonal Basis of Breast Cancer: Elevated Plasma Levels of Estrogen, Prolactin, and Progesterone. (Eng) Henderson, B. E. (Dept. Pathology, Univ. Southern California, Los Angeles, CA, 90033); Pike, M. C.; Gerkins, V. R.; Casagrande, J. T. In: *Incidence of Cancer in Humans. Proceedings of the Cold Spring Harbor Conferences on Cell Proliferation*. Hiatt, H. H.; Watson, J. D.; Winsten, J. A., eds. (Cold Spring Harbor: Cold Spring Harbor Laboratory): Origins of Human Cancer. Vol. 4, 602 pp.; 77-86; 1977.

The familial risk of breast cancer was studied in relation to a variety of hormone interactions. There was little difference in the physical characteristics or menstrual histories of 49 daughters of breast cancer patients and 46 daughters of control women. However, a bivariate scatter plot of prolactin and follicular phase total estrogen values showed that levels were clearly elevated in 12/34 daughters of patients vs only 1/30 daughters of controls. Luteal phase hormones were also elevated in the former in one study, but not in a second study, and the levels of plasma estrogen, progesterone, and follicle-stimulating hormone (FSH) were elevated in both studies. Nulliparity and a familial risk of breast cancer were increased in bilateral breast cancer patients diagnosed before age 40, and age at first pregnancy was increased in patients diagnosed between ages 40 and 49. Follicular phase estrone and FSH were significantly elevated in 18 daughters of bilateral breast cancer patients. It is concluded that the familial risk of breast cancer is associated with elevated levels of several hormones, including prolactin, progesterone, and estrogen. However, this 'intrinsic' risk is modified by age at first full-term pregnancy. (41 refs.)

78-7165 Seroepidemiologic Assessment of Feline Leukaemia Virus Infection Risk for Man. (Eng) Krakower, J. M. (Lab. RNA Tumor Viruses, NCI, Bethesda, MD, 20014); Aaronson, S. A. *Nature* 273(5662): 463-464; 1978.

The close environmental association of cats and humans and the known infectivity of feline leukemia virus (FeLV) for human cells in tissue culture prompted the examination of human sera for immunological evidence of exposure to this oncogenic agent. Radioimmunoprecipitation assays for antibodies to the major internal protein (p30) and envelope glycoprotein (gp70) of FeLV were performed with sera from 2,074 individuals, including healthy volunteers, subjects with occupational or home exposure to FeLV-infected cats, laboratory workers with occupational exposure to RNA tumor viruses (including FeLV), and patients with various neoplastic and other disorders. No individual had detectable antibodies against either FeLV protein. Sera from patients with hematologic malignancies and from subjects with known or potential home and occupational exposure to FeLV or FeLV-infected animals were further evaluated in competition radioimmunoassays for p30. None of these persons demonstrated detectable FeLV p30 antigen levels. It is concluded that FeLV infection occurs rarely, if at all, in the population studied. (16 refs)

78-7167 Leukemia in Olmsted County, Minnesota, 1965-1974. (Eng) Linos, A. (Dept. Medical Statistics and Epidemiology, Mayo Clinic, Rochester, MN);

Kyle, R. A.; Elveback, L. R.; Kurland, L. T. *Mayo Clin Proc* 53(11): 714-718; 1978.

An earlier study on the incidence of leukemia in Olmsted County, Minnesota, was extended to include 1965 through 1974. In this decade, the overall crude annual incidence rate was 9.5/100,000. The male:female ratio was 2.4:1, and the incidence rate in men was significantly higher than that in women, especially in the older age groups. Adjusted for age and sex, the mean annual incidence rate among men (17.3) was significantly higher than rates reported previously from other areas (ranging from 10.7 to 13), and it had increased significantly during 1935-1974. The increase was most prominent in men aged 50 yr and over, and it was detectable only in the subgroup with acute myelocytic leukemia. The observed number of farmers with leukemia (8) was significantly higher than that expected (2.8). (26 refs)

78-7177 **'Adult Type' Cancer in Children and Adolescents.** (Eng) Pratt, C. B. (St. Jude Children's Res. Hosp., P.O. Box 318, Memphis, TN, 38101); Johnson, W. W.; Hustu, H. O. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 961-970; 1977.

The incidence of "adult type" cancer was investigated among 1,009 children with malignant solid neoplasms admitted to a pediatric oncology center between March 1962 and January 1976. Fifty-eight of these patients, aged 3 mo to 19 yr, had tumors usually encountered only in adults. The median age of the 58 patients was 12 yr 9 mo; 22 were Caucasian boys, 18 Caucasian girls, 11 black boys, and 7 black girls. Thirty-seven patients had carcinomas (12 colon, 5 hepatocellular, 3 adrenal, 3 melanoma, 2 pancreas, 2 dysgerminoma, 2 teratocarcinoma, and 1 case each of parotid, thyroid, cholangiohepatocellular, kidney, rectum, seminoma, choriocarcinoma, and adamantinoma). Twenty-one patients had sarcomas (9 liposarcoma, 5 synovial, 2 schwannoma, 2 alveolar soft part, and 1 case each of histiocytoma, angiosarcoma, and mesenchymoma). During the same time period, 960 children were seen with acute lymphocytic leukemia, and 269 with nonlymphocytic leukemia. Among the solid tumor patients, 150 had Hodgkin's disease, 142 neuroblastoma, 127 non-Hodgkin's lymphoma, 99 Wilms' tumor, 99 rhabdomyosarcoma, 74 osteosarcoma, 75 Ewing's sarcoma, and 51 retinoblastoma. There is no indication that more pediatric

patients are being referred with adult-type cancers. However, the admission of nine patients with carcinoma of the bowel within a 15-mo period suggests an increasing frequency of this tumor among pediatric patients. Although almost all tumors that are more commonly seen in adults may occur in children, the occurrence of these rare tumors is of potential importance in regard to the implications of the changing diagnostic categories of patients referred to pediatric oncology centers. (17 refs)

78-7178 Gallbladder Disease and Gallbladder Cancer among American Indians in Tricultural New Mexico. (Eng) Morris, D. L. (Univ. Texas Sch. Public Health, Houston, TX); Buechley, R. W.; Key, C. R.; Morgan, M. V. *Cancer* 42(5): 2472-2477; 1978.

The incidence and mortality rates of gallbladder disease and gallbladder cancer were determined for American Indians (A-I), Spanish-Americans (S-A), and Anglo-Americans (A-A) in New Mexico using the data from the New Mexico Tumor Registry. The results confirmed previous reports of an extremely high incidence of gallbladder disease and cancer in A-I. Cases from the registry were used as numerators, data from the 1970 New Mexico population census as denominators; age adjustment was performed using the US standard population. Male mortality from noncancerous gallbladder disease was 15.3 for A-I and 2.8 for AA; the S-A were intermediate at 4.1. The distribution was similar for women. Computed gallbladder cancer incidence rates indicated a 15-fold increase for A-I vs A-A women, and a similar 6-fold increase in men. Again, S-A had intermediate rates. Standard incidence ratios were calculated for these groups, and indicated the magnitude of the differences between these populations. For A-A men and women, the ratios were 72.7 and 66.7, respectively. Analogous figures for A-I and S-A were 463.6 and 1,004.8, and 200.0 and 500.0. Several risk factors, including parity, obesity, age, cholesterol level, and genetic factors, were explored. Genetic factors appeared to be the most important, with parity a contributing factor. Thus, A-I may have a strong genetic disposition toward gallbladder disease and gallbladder cancer. This hypothesis might also explain the high rates in S-A, a high percentage of which have Indian ancestors. (20 refs)

78-7179 Occupational Dermatoses in the Uranium Industry. (Cze) Sevcova, M. (Kozni oddeleni, ZUNZ UP, 269 00 Pribram-Zdabor, Czechoslovakia). *Prac Lek* 30(4): 138-141; 1978.

The incidence of dermatoses was not increased in uranium industry workers, but the incidence of basal cell carcinoma was 3.6/10,000 (10.2/10,000 for > 5 yr exposure) vs an expected incidence of 0.8/10,000. (13 refs)

78-7180 Effect of a High Beef Diet on Bacterial Flora and Chemical Components of Human Feces: a Summary of Results. (Eng) Hentges, D. J. (Univ. Missouri-Columbia, Columbia, MO); Burton, G. C.; Flynn, M. A.; Franz, J. M.; Gehrke, C. W.; Gerhardt, K. O.; Maier, B. R.; Tsutakawa, R. K.; Wixom, R. L. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976*. International Study Group for the Prevention and Detection of Cancer (New York, NY): Vol. 1(part 1): 1193 pp.; 693-706; 1977.

To examine the effect of a diet high in beef on the bacterial and chemical composition of the feces of humans, 10 male student volunteers were placed on a 4-mo diet series consisting of a control diet, a meatless diet, a high-meat diet, and a second control diet, each of 1-mo duration. The diets were carefully formulated to standardize calories, proteins, fat, carbohydrates, cholesterol, fiber, minerals and vitamins. The fat and fiber content were held constant in all four diets. Total protein was the same in the control and meatless diets but was doubled in the high-meat diet. During the last week of each diet, three fecal samples were collected under oxygen-free conditions from each of the volunteers and analyzed for aerobic and anaerobic bacteria, proximates and minerals, individual amino acids, creatine and creatinine, tryptophan metabolites, polyamines, fatty acids, and neutral and acid steroids. Results showed that there was some increase in the proportion of anaerobic to aerobic bacteria in the feces during the high-meat diet, compared with the meatless diet. There was no increase in the concentration of neutral or acid steroids, and although the high-meat diet contained more cholesterol than did the meatless diet, significantly less cholesterol and fewer cholesterol metabolites were excreted during the high-meat regimen. The results fail to confirm the differences in flora composition and steroid concentration that have previously been observed between populations at high and low risk for colon cancer. (15 refs)

78-7181 Methodologic Issues in Epidemiologic Studies of Endometrial Cancer and Exogenous Estrogen. (Eng) Hulka, B. S. (Dept. Epidemiology and Biostatistics, Sch. Public Health, Univ. North Carolina, Chapel Hill, NC, 27514); Hogue, C. J.; Greenberg, B. G. *Am J Epidemiol* 107(4): 267-276; 1978.

Methodologic issues relevant to epidemiologic studies in general and to studies of the association between endometrial cancer and exogenous estrogen intake are discussed. Problems common to all epidemiologic studies concern pathologic misclassification of disease status; determination of the proper type, source, and amount of data to collect; studies of indications for therapy vs studies of the therapy as the cause of the disease; and differences in medical care in different populations. There are also problems associated with the prolonged follow-up of large numbers of patients and with deter-

mination of the appropriate population source from which to estimate the expected incidence of disease. Cohort studies may be biased by the fact that the two patient groups are not necessarily alike with respect to all possible confounding variables. Case-compeer studies have provided the primary epidemiologic basis for the current concern over increased risk of endometrial cancer associated with exogenous estrogen use. These studies involve matching endometrial cancer patients selected from community hospitals with noncancer or "other cancer" patients at the same hospitals or with ostensibly normal community women. They present problems in determining if the study cases are representative of all cases of the disease and in choosing a suitable comparison group from hospitals, the community, hysterectomized vs nonhysterectomized women, or women undergoing a common diagnostic procedure. The potential risk associated with estrogen use must also be weighed against possible benefits; this topic cannot be addressed by case-compeer studies. (23 refs)

78-7182 Low-Level Radiation and Cancer Deaths. (Eng) Sanders, B. S. (5823 Soledad Road, La Jolla, CA, 92037). *Health Phys* 34(6): 521-538; 1978.

The incidence of cancer among 17,600 men and 3,900 women who worked at the Hanford Works atomic plant in Richland, Washington, and were exposed to low levels of radiation was determined. For exposed men hired between 1944 and 1971, the mean radiation dose increased progressively from 142 millirems (mrem; rem = roentgen-equivalent-man) in 1944 to 3,745 mrem in 1972; the percentage of deaths from cancer was 19.85 for 1944-1959 and 20.27 for 1960-1972. For those hired in 1944 and 1945, the observed dose gradient rose from 142 mrem in 1944 to 3,762 mrem in 1972; the percentage of cancer deaths was 20.67 for 1944-1959 and 19.10 for 1960-1972. From the time of hire to October 1972, the percentage of deaths from cancer was 20.36 for men hired between 1946 and 1971 and 20.05 for those hired in 1944 and 1945. For each year, the mean dose level of those who died from cancer was not significantly different from the mean of those who died from other causes. The mean dose level for the majority of those who died in a specific year was lower than the mean for survivors in the year of death or in the 1 or 2 yr preceding the year of death. Similar findings were observed among the female employees. Although male employees with radiation exposure had a higher proportion of cancer deaths than the general male population in the state of Washington, there was no indication that the radiation was the cause of this difference. Further studies of exposed men vs nonexposed male employees, and out-of-plant controls indicated that the exposed employees had a greater longevity than identified siblings of such employees, nonexposed employees, and matched controls. Thus, all observations to date indicate no adverse health effects among employees that can be attributed to occupational radiation exposure within permissible limits. (17 refs.)

78-7183 Measurement of Environmental Nitrosamines. (Eng) Cohen, J. B. (Natl. Enforcement Investigations Center, Office Enforcement, U.S. Environmental Protection Agency, Denver, CO); Bachman, J. D. *IARC Sci Publ* (19): 357-372; 1978.

The results of a sampling program designed to identify sources of direct emission of nitrosamines (NA's) into the environment and to assess environmental formation of NA's are presented. Samples were taken during summer and winter in the proximity of industrial plants, primarily sources of amines, and analyzed for NA's. There was little indication of the presence or formation of N-nitroso compounds in the air in the vicinity of the sources examined, even when these compounds were observed in plant wastewater. The wastewater samples indicated that N-nitroso compounds are present in chemical, pesticide, and coke plant effluents, some persistently. The in situ sampling did not present any evidence to substantiate secondary production in the vicinity of amine sources. There were no data that would indicate the formation of NA's in the environment, as opposed to their presence as a contaminant. Samples collected along and transverse to major highways showed no contribution of NA's from engine exhaust. The presence of NA's in deionized water (introduced by the mixed-bed resins used for deionization) constitutes a potential, long-term risk for the general population. (9 refs)

78-7184 Dietary Aflatoxins and Human Primary Liver Cancer. (Eng) Peers, F. G. (Tropical Products Inst., 56-62 Gray's Inn Road, London WC1X 8LU, England); Linsell, C. A. *Ann Nutr Aliment* 31(4/5/6): 1005-1018; 1977.

The combined results of two studies, one performed in the Murang'a district of Kenya and the other in Swaziland, show a high degree of positive correlation between calculated ingestion levels of aflatoxin, expressed as nanograms/kilogram/day (x), and the adult incidence rates of hepatocellular carcinoma, expressed as cases/10⁵ adults/year (y). This positive correlation is true for both men and women. Based on an assumed 2-kg/day intake of wet diet at a mean body wt of 70 kg, the calculated relationship for adult women is: $y = 4.14 \log_{10} x - 0.80$. With the added assumption of a daily intake of 2 liters/day of native beer, the regression equation for adult men is: $y = 21.96 \log_{10} x - 11.17$. These regression data are essentially compatible with comparable data recorded by independent workers in Thailand and Mozambique, the latter being the region where the highest rates of liver cancer and the highest aflatoxin ingestion levels have been recorded to date. A highly significant regression line was also calculated using crude liver cancer incidence data and aflatoxin exposure levels from all available studies: $y = 7.60 \log_{10} x - 3.60$. (27 refs)

7185 **Variable Globin Chain Synthesis in Mouse Erythroleukemia Cells.** (Eng) Alter, B. P. (Div. Hematology and Oncology, Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA, 02115); Goff, S. C. *Leukemia* 52(5): 1047-1057; 1978.

Various mouse erythroleukemia cell (ELC) lines were treated with chemical inducers to determine the proportion of β minor globin (β -MG) synthesis. When cultured with 2% methylsulfoxide, cell lines 745 and 707 from DBA/2 mice synthesized 25%-48% β -MG (75%-52% β -major globin). Induction of the same cells with butyric acid (1 millimole) led to approx 40% β -MG production, but induction with hemin (75 μ M) resulted in > 80% β -MG synthesis. ELC lines derived from other mouse strains show variations in the proportions of globin chains, compared with those from DBA/2 mice, when subjected to similar treatment. The chemical inducing agents did not influence protein stability or the initiation of globin synthesis. Translation of poly(A)-containing cytoplasmic RNA in a wheat germ-free system resulted in the same proportions of β -MG as those seen in intact cells. It is concluded that the induction of globin production depends on the specific interaction of erythroid pre-

cursors with the inducing agents and is due to the regulation of transcription, differential posttranscriptional stabilization of messenger RNA, or the selective proliferation of cells whose specific type of globin production is predetermined. (37 refs)

Biology and Physiology, Silesian Medical Acad., 41 808 Zabrze, Poland); Piskorska, D.; Jerzykowski, T. *Neoplasma* 25(4): 465-470; 1978.

Glyoxalase I and II activities were determined in the livers and tumor cells of BDF₁ and DBA₂ mice bearing implanted sarcoma 180 and L1210 leukemia in ascites form. The ascites fluids had been injected into the peritoneal cavity. No glyoxalase II activity was detected in the cells of either tumor, but glyoxalase I activity was reduced in comparison with that in normal tissues. Hepatic glyoxalase I and II activities decreased progressively during tumor development. This reduction was as high as 40%-60% of the initial levels. The results corroborate previous findings on the absence or reduction of glyoxalase activity in tumor cells and in the liver during tumor development, and they indicate that a tumor developing ip affects glyoxalase activity in the liver, an organ not directly attacked by the tumor. A discussion is presented of the implications of the recently discovered enzymatic imbalance in the cancer cell. The prevalence of catabolism over anabolism in the tumor cell confirms the hypothesis that the impaired metabolism of the tumor cell can be measured in terms of changes in the balance of activity of adenylcyclase vs activity of guanylcyclase. - 78-7189 **A Comparison of Polysomal Messenger Ribonucleoprotein Particles from Normal and Neoplastic Rat Liver.** (Eng) Cardelli, J. A. (Dept. Oncology, McArdle Lab. Cancer Res., Medical Sch., Univ. Wisconsin, Madison, WI, 53706); Pitot, H. C. *Cancer Res* 38(7): 2099-2102; 1978.

Free polysomes were isolated from normal and regenerating rat liver and from Morris hepatomas 7777, 7800, 5123C, and

9618A and compared in terms of their messenger ribonucleoprotein particles (MRP). Sucrose gradient analysis ruled out the possibility of any significant messenger RNA (mRNA) degradation in these polysome preparations, since the polysomes were relatively large (8-12 ribosomes/mRNA) and the tissues contained only small amounts of disomes. The EDTA-disrupted polysomes were fractionated on oligodeoxythymidylic acid-cellulose columns. The column-bound polyribadenylic acid-containing MRP were eluted with a formamide buffer, precipitated with ethanol, and subjected to polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulfate. The mRNA-associated proteins from the different tissues were qualitatively similar, but two proteins with a mol wt of 66,000 and the 109,000, which were found as minor proteins in normal liver, appeared on gels as major protein bands when hepatoma MRP were examined. The two proteins were also minor proteins in regenerating and host liver MRP, suggesting that their increase in the hepatomas was not due to tissue growth or to exposure to an altered hormonal environment per se. The possibility exists that the increase in certain MRP is related in some way to the initiation and/or maintenance of the neoplastic state. (15 refs)

- 78-7190 **Analysis of RNA Initiated in Isolated Mouse Myeloma Nuclei Using Purine Nucleoside 5' [γ-S] Triphosphates as Affinity Probes.** (Eng) Smith, M. M. (Dept. Molecular Biology, Univ. Edinburgh, King's Buildings, Mayfield Road, Edinburgh, Scotland EH9 3JR); Reeve, A. E.; Huang, R. C. *Cell* 15(2): 615-626; 1978.

The purine ribonucleoside triphosphate analogs adenosine 5' [γ-S] triphosphate and guanosine 5' [γ-S] triphosphate were used as affinity probes to study RNA chain initiation in isolated nuclei from the mouse myeloma 66.2 cell line. The binding was specific and dependent on inclusion of the sulfur nucleotide analogs in the in vitro synthetic reaction. The affinity-labeled RNA appeared to be initiated in vitro. The nuclei incorporated 1.2-2.4 picomoles of uridine monophosphate/10⁶ nuclei/min, and the rate of synthesis was unaffected by substitution of the nucleotide analogs for the normal nucleotides. The percentage of total RNA synthesized that was incorporated into sequences initiated in vitro was 7.8%-9.6%. The size of the total RNA synthesized ranged from <5S to 45S, and the size of the affinity-labeled sequences ranged from <5S to 28S. The incorporation into RNA initiated in vitro was abolished by α-amanitin in concentrations inhibitory for polymerase II or III. Over 70% of the total incorporation into ribosomal 5S RNA transcripts was into sequences initiated in vitro. This initiation was catalyzed by polymerase III and was specific for guanosine triphosphate as the initiating nucleotide. The RNase T1 fingerprint of the newly initiated 5S RNA indicated that this gene was accurately initiated and elongated in vitro. (52 refs)

78-7191 **Circulating DNA and Oncogenesis.** (Eng) Anker, P. (Div. Oncohaematology, Dept. Medicine, Cantonal Hospital, Geneva, Switzerland); Stroun, M.; Maunula, P. In: *Third International Symposium on the Detection and Prevention of Cancer held by the International Study Group for the Prevention and Detection of Cancer in New York, April 26-May 1, 1976.* International Study Group for the Prevention and Detection of Cancer (New York, NY): 1977. 1(part 1): pp. 1193; 3-16; 1977.

The DNA released from eukaryote cells (reDNA) was characterized, and the possible existence of circulating DNA was explored. The material released from frog auricles and from human blood lymphocytes had the UV absorption characteristics of cellular DNA and was 95% digested by DNase but insensitive to RNase and pronase. The mol wt of the reDNA was not as homogeneous as that of cellular DNA: the latter had one peak over 18S, but reDNA had two main peaks of about 12S and 7S. Separation on CsCl gradients indicated that the AT/GC ratio was the same for both DNA's. The reDNA was not due to a DNA loss from damaged cells, and there was constant renewal of extracellular DNA with each change of medium, suggesting that release is governed by a precise homeostatic mechanism. The DNA was released in a complex containing proteins, among which were enzymes necessary for partial extracellular synthesis of reDNA. Near-neighbor analyses showed that this extracellular synthesis was a true synthesis. The spontaneous transfer of DNA from bacterial to higher organisms that occurs during bacterial infection and its subsequent transcription might be a general biological process that occurs between eukaryote cells in normal conditions, and it suggests the existence of circulating DNA. In view of the fact that DNA extracted from malignant cells can transform normal cells, an oncogenic role of circulating DNA is postulated. It is possible that a circulating DNA may not necessarily be transforming but might be involved in changes associated with malignancy. (29 refs)

78-7192 **In Vitro Cell Proliferation Studies in Hodgkin's Disease.** (Eng) Cowley, J. G. (Natl. Inst. Oncology and Radiology, Havana, Cuba). *Neoplasma* 25(1): 3-90; 1978.

DNA replication in lymph node cells from 30 untreated Hodgkin's disease patients was studied autoradiographically using two different tritiated thymidine pulse-labeling techniques. Nine patients with inflammatory reactive conditions served as controls. The results confirmed previous labeling data, but they showed that DNA synthesis can also be detected among the reticulum cells. Cell proliferation in Hodgkin's and Reed-Sternberg cells appeared to be a characteristic of large mononuclear elements even though some multinuclear elements were detected in DNA synthesis. Large multipolar mitoses were frequent in the Hodgkin's patients, which suggested that the multinuclear cells may have evolved from the mononuclear cells. (17 refs)

78-7194 **Coordinated Regulation of Octopine Degradation and Conjugative Transfer of Ti Plasmids in *Agrobacterium tumefaciens*: Evidence for a Common Regulatory Gene and Separate Operons.** (Eng) Klapwijk, P. M. (Dept. Biochemistry, State Univ. Leiden, 2300 RA Leiden, Netherlands); Scheulderman, T.; Schilperoort, R. A. *J Bacteriol* 136(2): 775-785; 1978.

In an attempt to determine whether octopine utilization is genetically related to conjugative *Agrobacterium tumefaciens* Ti plasmid transfer by the functioning of a shared regulatory mechanism and whether there is a correlation between the genes responsible for octopine metabolism and tumorigenesis, the analog noroctopine was used to isolate *A. tumefaciens* mutants with altered regulatory patterns for Ti plasmid-associated degrading genes. Results of cointegration, conjugation, and octopine oxidase and permease enzyme assays revealed three distinct mutant groups: (1) those with a constitutive level of octopine enzymes and a high degree of spontaneous Ti transfer; (2) those with high enzyme levels but not transfer; and (3) those in which both conjugation and octopine utilization were induced by noroctopine. It was concluded that these results were due to the activity of a common gene. Additionally, when homo-octopine was used to produce mutants defective in octopine metabolism, strain virulence was dependent on the ability to transfer the Ti plasmid. The results indicate that conjugative transfer does not play a significant part in crown gall tumor induction in plants. (38 refs)

78-7197 **Mitogens for Murine Embryo Cell Lines.** (Eng) Herschman, H. R. (Sch. Medicine, Univ. California, Los Angeles, CA, 90024); Passovoy, D. S.; Pruss, R. M.; Aharonov, A. *J Supramol Struct* 8(3): 263-268; 1978.

The growth-promoting activities of fetal bovine serum, cortisol, phorbol myristate acetate (PMA), prostaglandin F₂, insulin, epidermal growth factor (EGF), and fibroblast

growth factor (FGF) were evaluated in four murine embryo cell lines (Swiss 3T3, BALB 3T3, M2, and C3H10T1/2). All cell lines showed an increased saturation density when grown in progressively higher serum concentrations, but the M2 cell line demonstrated a somewhat reduced response to serum in comparison with the other three lines. The results were variable: positive results for most mitogens ranged from 50% to 100% increases in cell numbers. PMA was mitogenic for both Swiss 3T3 and M2 cells but not for 10T1/2. Prostaglandin F₂ was mitogenic only for Swiss 3T3 cells, but cortisol was inactive in all four lines. Insulin was stimulatory only for Swiss 3T3 cells, and then only at very high concentrations when compared with other polypeptide mitogens. A 50% increase in saturation density occurred in Swiss 3T3 cells in response to 1 ng/ml of EGF, whereas a similar growth response was elicited only with 1,000-10,000 ng/ml insulin. At 100 ng/ml, EGF resulted in mitogenic responses of 172%, 284%, 127%, and 312% in Swiss 3T3, Mw, C3H10T1/2, and BALB 3T3 cells, respectively. At 10 ng/ml, FGF caused increases of 144%, 121%, 85%, and 122% in the respective cell lines; at 100 ng/ml the corresponding values were 217%, 199%, 122%, and 171%. These experiments show that serum, EGF, and FGF stimulate cell division in all four lines, albeit to varying degrees for the different target cells. (23 refs)

- 78-7198 **Sulfated Mucopolysaccharides from Normal Swiss 3T3 Cell Line and Its Tumorigenic Mutant ST1: Possible Role of Chondroitin Sulfates in Neoplastic Transformation.** (Eng) Dietrich, C. P. (Departamento de Bioquímica e Farmacologia, Escola Paulista de Medicina, Caixa Postal 20372, Universidade de São Paulo, Brazil); Armelin, H. A. *Biochem Biophys Res Commun* 84(3): 794-801; 1978.

The surface sulfate mucopolysaccharides (MPS) of normal Swiss 3T3 cells and a glucocorticoid-sensitive Swiss 3T3 tumor mutant (ST1) were compared. MPS were labeled by incubation with Na₂³⁵SO₄ (10 µCi/ml), cultured, trypsinized, and analysed by agarose gel electrophoresis and enzymatic degradation with appropriate enzymes. Normal 3T3 cells contained primarily chondroitin sulfate B (CSB) (49% in whole cells) and heparin sulfate (HS) (40%), plus small amounts of CSA (11%). The ST1 mutant contained chondroitin sulfate A (CSA) (43%), HS (44%), and small amounts of CSB (13%). After the addition of hydrocortisone to ST1 cell cultures, the cells showed some of the properties of normal cells (cell density, anchorage, and serum dependence), but their sulfated MPS composition remained constant. Degradation of normal and ST1 cells with chondroitinases B and ABC showed that they contained only 4-sulfated disaccharides. Normal Swiss 3T3 and 3T6 cells, both of which undergo spontaneous transformation with time in culture, showed increased CSA and decreased CSB after exhibiting phenotypic characteristics of transformation, including loss of contact inhibition. These results support the hypothesis that glucuronic acid-containing CSA A plays a role in the

stimulation of cell division in neoplastic and embryonic tissues. (19 refs)

- 78-7199 **Establishment and Characterization of a New Human Urinary Bladder Carcinoma Cell Line (PS-1).** (Eng) Sanford, E. J. (Div. Urology, Dept. Surgery, Milton S. Hershey Medical Center, Pennsylvania State Univ., Coll. Medicine, Hershey, PA, 17033); Geder, L.; Dagen, E.; Laychock, A. M.; Ladda, R.; Rohner, T. J. *Invest Urol* 16(3): 246-252; 1978.

An epithelioid cell line (PS-1) was established from a human transitional cell carcinoma of the urinary bladder. Sc injection of the epithelioid cells into weanling athymic nude mice induced solid tumors histologically similar to the original tumor. A cell line was also established from a tumor induced in an athymic nude mouse (PS-1, T-1). Both cell lines exhibited essentially identical growth characteristics and formed monolayer growth of epithelioid cells in culture. Electron microscope studies confirmed the epithelioid morphology. No fibroblastoid elements were observed. Chromosomal analysis revealed heteroploidy with persistent marker chromosomes. All cells contained a Y chromosome. The presence of a tumor-specific antigen(s) in PS-1 cells was suggested by radioimmunoassay and cytotoxicity assays with peripheral allogeneic lymphocytes from other transitional cell cancer patients. Serum from urinary bladder cancer patients reacted with nuclear antigens of the established cells. (22 refs)

- 78-7200 **Serum Ribonucleases in Pancreatic Cancer: Correlation to Tumor Histology.** (Eng) Funakoshi, T. (Third Dept. Internal Medicine, Faculty Medicine, Kyushu Univ., 1-1 Maeda-shi 3-chome, Higashi-ku, Fukuoka City 812, Japan); Wakasugi, H.; Kimura, T.; Matsumoto, M.; Ibayashi, H. *Gastroenterol Jpn* 13(5): 390-394; 1978.

Serum ribonuclease (RNase) levels of 18 normal persons, 18 patients with chronic pancreatitis, and 26 patients with pancreatic cancer were determined using polycytidylic acid as substrate. The RNase levels of patients with four histologic types of pancreatic cancer were compared, ie, in patients with ductal cell adenocarcinoma, and anaplastic cell, acinar cell, and islet cell carcinoma. The normal level of serum RNase was 92 ± 6.3 units (U). In chronic pancreatitis and pancreatic cancer it was 118 ± 10.4 and 249 ± 16.8 U, respectively. Patients with ductal cell adenocarcinoma had the highest serum RNase levels. The phosphocellulose chromatography patterns of the serum RNase and pancreatic cancer tumor extract were compared with those of serum RNase and pancreatic extracts from normal subjects. Control serum and control pancreatic extract both exhibited three main elution patterns, but pancreatic cancer serum and tumor extract exhibited a different elution pattern and high activity. It is suggested that enzyme elevations may be due to the synthesis of a new species of RNase and an increased enzyme synthesis by the proliferating tumor cells. If this theory proves correct, early diagnosis of pancreatic cancer may be accomplished by analyzing serum RNase isozymes. (13 refs)
